## WHITE-TAILED DEER

## Historical Perspective

White-tailed deer (Odocoileus virginianus) were reported to be abundant when European settlers arrived in Iowa in the early 1800's. Although the clearing and cultivating of land for agriculture may have initially improved the suitability of the landscape for deer, uncontrolled exploitation for food and hides rapidly reduced deer numbers. By 1880 deer were rarely sighted in much of the state and in 1898 the deer season was legally closed. By this time deer had been virtually eliminated from all parts of the state.

Re-establishment of deer into the state can be traced to escapes and releases from captive herds and translocation and natural immigration from deer herds in surrounding states. A conservative estimate of the population in 1936 placed statewide numbers at between 500 and 700 animals. This small herd grew steadily. By 1950 deer were reported in most counties and the statewide estimate topped 10,000 . Concentrations in some areas were beginning to cause problems by damaging agricultural crops in addition to some complaints concerning deer/vehicle collisions. In response to these problems the first modern deer season was held in December of 1953 and 4,000 deer were killed. The harvest in 1996 exceeded 100,000 for the first time ever.

Although deer are frequently associated with forested areas, they are very adaptable and will utilize many different types of habitat as long as the area provides adequate cover. Examples of these types of areas include brushy draws and fence lines, marshes, and grassy areas like those provided by the federal Conservation Reserve Program (CRP).

Standing corn also provides ideal habitat for part of the year since it provides cover and food during portions of the growth cycle. Urban environments can also prove to be good habitat for deer, especially if there are green belts, parks or other natural spaces nearby.

Deer utilize almost all plants for food at one time or another during the year. Deer feeding habits can best be described as being widely selective as deer will sample many plants while feeding but often utilize a single, palatable source of food for the majority of their diet seasonally. Preferred foods change throughout the year in response to changing metabolic demands and forage availability.

The whitetail's ability to thrive in Iowa is likely the result of abundant, reliable food sources and a winter climate where snow depths rarely exceed 12 " for a prolonged length of time. Droughts are also rare and do not impact the availability of food like they do in some areas of the United States. These factors combine to allow deer to come through the "winter bottleneck" in excellent condition. The excellent nutrition also enables deer to have high reproductive rates. Many does in Iowa give birth to a single fawn at one year of age and 2 fawns each subsequent year. Deer in the wild can maintain these high reproductive rates past 10 years of age. Research in Iowa has found that 8 to $12 \%$ of adult does have 3 fawns.

Another reason that deer do so well in Iowa is that they are very mobile. Although many deer never move far from the area where they were born, a significant number ( $10-20 \%$ on average) leave and travel to new areas before establishing a core area. These core areas
may change seasonally with deer shifting between wintering areas and fawning areas. These movements allow deer to fill voids left open due to deaths and changing habitat. Thus deer easily pioneer into new areas when habitat is suitable. The highest rates of movement occur during 2 periods of the year. The first is in the spring when does move to their fawning areas. Many of the previous year's fawns find areas of their own at this time. The second period is in the fall during the breeding season. The breeding season or rut begins in mid-October and runs through mid-January, although the peak of activity occurs in mid-November.

Careful management of deer populations by man has also played an important role in allowing deer numbers to return to the levels enjoyed today. Management consists primarily of regulating the doe harvest since hunting provides the major source of mortality for deer in modern day Iowa. Unchecked, Iowa's deer herd could grow at a rate of $20 \%$ to $40 \%$ each year. At this rate, deer numbers would double in as few as 3 years. With Iowa's long growing season and agricultural crops providing abundant food, densities could exceed 100 or more deer per square mile in year-round deer habitat before natural regulatory mechanisms would begin to affect deer health and slow the rate of growth. Deer numbers this high would cause severe economic hardship to Iowa's landowners as well as alter the natural vegetative community. Maintaining a deer population in balance with the differing and often competing wants and needs of the people in the state is a difficult task and hunting is the only viable management option to achieve this goal.

## 2013-2014 Hunting Season Results

The reported kill for the 2013/14 season was 99,414 (Table 1.1) which is about $5 \%$ lower than in 2012 (Table 1.2). There were 18,496 fewer deer licenses issued for the 2013/14 deer season compared to 2012/13. There were 9,829 fewer antlerless licenses and 8,667 fewer any-deer licenses. Antlerless licenses made up about $37 \%$ of the deer licenses issued during the 2013/14 deer season.

The reduction in license sales and harvest is likely related to lower deer numbers, colder than normal weather in December and January and reduced antlerless quotas in some counties. The number of hunters declined by $3 \%$ from 2012 and is $4 \%$ lower than the peak in 2006.

The highest harvest estimate occurred in 2005 but was based upon a statistically designed post-season survey. The new harvest reporting system is not directly comparable. Its comparability with the former system were discussed in detail in the 2006/07 annual deer report.

Antlerless deer represented $60 \%$ of the 2013 harvest and about $50 \%$ of the total harvest was comprised of does (Table 1.1). This was a $1 \%$ increase for antlerless deer and a $2 \%$ increase in does when compared to the 2012 season. Seven percent of the reported doe kill occurred during the January antlerless season. The reported number of antlered deer in the harvest was $17 \%$ lower than in 2012 and represented $40 \%$ of the 2013 harvest (shed-antlered bucks are included in this statistic). There were 894 shed-antlered bucks reported which represented about $2 \%$ of the total buck harvest.

Information (registration numbers, age and sex, county of kill, etc.) was collected from about 1,725 deer checked
in the field and at lockers to determine what proportion of successful hunters reported their deer. Examination of this data indicated that $85 \%$ of the harvested deer that were encountered in the field were reported. This was the same as the 2012 season.

There is likely a bias in the above rate since all of these situations require the hunter to take the deer to a locker or have contact with a DNR official or someone in an official capacity. Making some allowance for the potential bias, it is estimated that about $80 \%$ of the deer harvested in 2013/14 were properly reported.

Figure 1.1 compares the harvest reporting system (a known minimum harvest level) with the post-season postcard survey harvest estimates conducted prior to the 2006 hunting season. The figure shows what the actual harvest might have looked like using the calculated relationship between the two systems.

The reported harvest declined by about $14 \%$ when compared to 2012 and is $34 \%$ lower than in 2006 (Figure 1.2).

The general season framework did not change from 2012 (Table 1.6). Centerfire rifles could be used during the January Antlerless season in the 21 southernmost counties (Figure 1.3). Landowners could get 1 reduced price either-sex license and up to 4 reduced price antlerless licenses in addition to the regular tags a deer hunter could legally obtain. Seventy-two counties had additional antlerless licenses available. Twenty-seven counties in northern and central Iowa had no antlerless quota. Hunters in all seasons could obtain an unlimited number of antlerless licenses but were limited to the purchase of one antlerless license prior to

September 15th. Antlerless licenses were restricted to a specific county and season.

About 2,100 deer were taken during special management hunts in urban areas and in state and county parks (Table 1.7). Approximately 1,800 deer were reported by hunters using special antlerless depredation licenses that were allotted to hunters on land where landowners were experiencing crop damage problems. Authorization numbers are issued to the landowner who can then distribute them to hunters who use them to purchase a depredation license.

Five of the top 10 counties for total kill were in the northeast portion of the state in 2013 with the remainder being in southern and central Iowa. Clayton was again the top county for total reported kill with 4,091 deer or about 5.3 deer harvested per square mile (Tables 1.4). Van Buren County had the highest kill per square mile of area at 5.6 deer per square mile. Grundy County had the lowest kill with a reported 91 deer or about 0.2 deer per square mile.

Tissue samples were gathered and tested from 4,040 wild deer for chronic wasting disease (CWD) surveillance purposes. The majority of the samples were obtained during the shotgun seasons with concentrated efforts in northeastern Iowa as the disease occurs in neighboring wild deer populations in Illinois and Wisconsin. Two southern Iowa counties (Appanoose \& Wayne) also received concentrated sampling efforts in captive whitetails in Linn and Macon counties, Missouri in 2010 and 2012 respectively. Concentrated surveillance efforts were also in place in Howard, Mitchell, and Winneshiek counties in 2013 in response to one wild whitetail testing positive in Olmstead County, Minnesota near Pine Island in 2012. Lastly, surveillance was increased in the areas of Davis, Wapello Cerro Gordo, and Pottawattamie counties
in response to CWD being found in captive whitetails in 1 facility in each of these counties in 2012.

On April 8, 2014, notification was received from NVSL confirming CWD in a sample collected from an adult wild male white-tailed deer harvested during the fall firearms season in Allamakee County in northeast Iowa. This is the first positive from wild deer to date in Iowa.

Tissue samples were also collected from 304 captive whitetail deer, 4 freeranging elk, 1 red deer and 1 fallow deer in 2013/14 and CWD was not detected in any of these samples.

Since 2002, Iowa has tested 50,998 wild deer and 3,429 captive deer and elk.

## Shotgun Season

The reported kill during the shotgun seasons was about $5 \%$ lower than the reported harvest in 2012 (Table 1.2). The reported harvest has declined for the last 7 years. Overall, hunting conditions were fair however extremely cold weather during the opening weekend may have suppressed hunter activity. Fewer deer were reported during both seasons compared to 2012.

Antlered bucks made up about $38 \%$ of the total kill, while does made up $50 \%$ of the kill. Button bucks made up about $11 \%$ of the reported harvest and shed-antlered bucks accounted for less than $0.5 \%$.

There were 71,169 paid resident licenses sold for the first season and 25,530 deer were reported killed, while 61,439 paid resident licenses resulted in 16,912 deer reported during the second season. The reported success rate for first season hunters was $36 \%$ while second season license holders reported $28 \%$ success.

Antlered bucks made up $46 \%$ of the harvest in the first season harvest while
does made up 46\%. During the second season, does make up the majority of the harvest at $52 \%$. Antlerless deer made up $57 \%$ of the reported kill during the first season and $65 \%$ of the kill during the second season.

The reported deer kill per square mile (Figure 1.4) was highest in northeastern and southern Iowa as would be expected due to deer densities and hunting opportunities.

Less than $50 \%$ of the kill in most counties in northwest Iowa were does (Figure 1.5). However, over 50\% of the harvest were does in southern and eastern Iowa.

Assuming that any biases in reporting are similar across the state (which the data suggests), some generalizations can be made regarding current deer management and harvest strategies. Current regulations continue to be effective in allowing more antlerless deer to be taken in southern and eastern Iowa (Figure 1.4). The deer seasons and antlerless quota allocations for 2013 also maintained higher levels of doe harvest in the targeted areas of the state (Figure 1.5) as the doe harvest approaches or is over $50 \%$ of the harvest in the vast majority of these counties.

## January Antlerless Season

There were 38 counties open for the January antlerless season (Figure 1.3) in 2013/14 season. All licenses issued for this season were for antlerless deer only. The season was the same length for all counties (11-19 January) and centerfire rifles could be used during the entire season in the southern two tiers of counties. A total of 17,219 licenses were issued, which is $14 \%$ less than the previous year with $25 \%$ of them being reported as filled (Table 1.1 and 1.2). Licenses for this season did not go on
sale until December 15th.
The total harvest was a $21 \%$ lower than $2012 / 13$. The reported kill during this season accounted for $4 \%$ of the statewide total kill and does harvested during the January antlerless season represented about $7 \%$ of the total doe harvest.

However, the impact in many counties was much greater. For example, the harvest during this season represented $18 \%$ of the reported county kill and $35 \%$ of the doe kill in Taylor County. In most southern Iowa counties the harvest during this season represented from $10-30 \%$ of the total doe harvest for the county (Figure 1.6). Hunters reported that $79 \%$ of the deer taken were does and about $14 \%$ were buck fawns and shed-antlered bucks made up $7.9 \%$ of the reported harvest. The season accounted for $34 \%$ of the total number of shed-antlered bucks reported during the 2013/14season.

## Archery

The reported harvest for 2013 was about 20,278 deer including the deer killed on the senior cross bow license. The harvest was $8 \%$ lower than in 2012 (Table 1.1 and 1.2). The number of licenses issued decreased by $1 \%$ from the previous year to 89,286 . Hunters reported that $27 \%$ of the antlerless licenses were used to tag a deer and the overall reported success rate was $23 \%$ which is slight lower than in 2012.

Sixty percent of the deer taken by archers were male and $52 \%$ were antlered bucks (includes shed-antlered bucks, Table 1.9).

## Muzzleloader

The reported kill during the early muzzleloader season was 4,027 (a $3 \%$
increase from 2012) and license sales were $1 \%$ lower than in 2012 (Table 1.1 and 1.2). About $34 \%$ of the licenses purchased were reported to have been used to tag a deer. Bucks made up $52 \%$ of the kill, with antlered bucks making up about $44 \%$ of the total (Table 1.10).

The reported kill during the late muzzleloader season was 6,828 (Table 1.1 and 1.2 ) which represented a decrease of $33 \%$ from the 2012 reported harvest. Fiftythree percent of the deer reported were does and $34 \%$ of the deer killed during the late muzzleloader season were antlered bucks (includes shed-antlered bucks).

## Nonresidents

Of the 6,025 any-deer licenses issued, 2,830 or $47 \%$ went to hunters during the shotgun seasons, 2,096 or $35 \%$ to bowhunters and 1,025 or $17 \%$ to late season muzzleloader hunters. All of these nonresident hunters also received an antlerless-only license.

The reported success rates for the any-deer licenses were $43 \%$ for the shotgun licenses, $35 \%$ for the late muzzleloader licenses and $40 \%$ for the archery licenses. The reported success rates for the antlerless-only licenses held by these hunters were $32 \%$ for the shotgun licenses, $20 \%$ for the late muzzleloader licenses, and $18 \%$ for the archery licenses.

An additional 2,603 optional antlerless-only licenses were issued to nonresidents. Of these, 2,366 went to shotgun hunters, 179 went to hunters participating in the holiday season (12/24 $1 / 2 / 14$ ), and 59 licenses were purchased for the January antlerless season. The reported success rates for the optional antlerless licenses were $36 \%$ for the shotgun seasons, $33 \%$ for the holiday antlerless season, and $43 \%$ during the January season.

Collectively, the success rate for all the nonresident antlerless licenses issued during the shotgun seasons was $28 \%$.

In total, nonresidents reported harvesting 2,438 antlered bucks, 2,148 does, and 262 button bucks. The reported success rate for all licenses was $33 \%$ and $44 \%$ of the overall harvest by nonresidents consisted of does.

## Special Youth \& Disabled Hunter Season

The total number of licenses issued $(11,019)$ for this season was $4 \%$ higher than in 2012 (Table 1.1 and 1.2). Disabled hunters were issued 377 of the licenses which was a $2 \%$ increase from 2012. Youth season hunters who did not take a deer during the youth deer hunting season were able to use the deer hunting license and unused tag during the early or late muzzleloader seasons or one of the two shotgun seasons. Also, an either-sex deer license purchased by either a youth or disabled season hunter did not count towards the maximum number of any-deer licenses allowed in Iowa.

The success rate was $41 \%$ with 3,425 deer registered (a $13 \%$ decrease from 2012). About $50 \%$ of the deer reported were antlerless and the reported harvest consisted of $41 \%$ does.

## Special Deer Management Zones

Special management hunts were conducted at 53 locations in 2013/14and about 2,325 deer were reported (Table 1.7). These hunts are designed to meet the management needs of areas such as state and county parks and urban areas that are not suitable to be opened to general regulations. Almost all deer taken were antlerless and deer tagged did not count against a hunter's regular licenses or bag
limit. Most hunts were very successful in removing deer in these problem areas.

An additional 3,786 licenses and permits were issued to hunters/landowners in depredation situations which resulted in the reported harvest of 1,807 deer. This is a $25 \%$ decrease in the depredation harvest from 2012/13.

## Population Trend Surveys

Three techniques are currently used to monitor trends in Iowa deer populations. These are 1) spotlight surveys conducted in April, 2) a record of the number of deer killed on Iowa's rural highways throughout the year coupled with annual highway use estimates, and 3) the bowhunter observation survey conducted during October-November. All of these surveys correlate well with the reported harvest estimates and appear to provide reliable long-term trend indices. However, none of these surveys can be considered absolutely reliable indicators of annual changes in the population because of the high variability in the survey conditions, deer behavior, habitat conditions and weather.

Deer populations for the state as a whole have declined (Figure 1.7). This is due to the dramatically increased harvest pressure that has been applied to the female segment of the herd beginning with the 2003 hunting season. The goal was to return deer population levels to those that existed in the mid-to-late 1990s. This goal has been achieved on a statewide basis.

The winter aerial deer trend surveys were discontinued in 2013. Although utilized for a period of 30 years in Iowa, these trend surveys overall had the lowest correlation values in the model analyses and were replaced with new trend indices.

The number of deer killed on rural highways decreased by about $11 \%$ in 2013.

The estimated number of vehicle miles driven increased slightly in 2013 when compared to 2012 and the resulting adjusted road kill (kills per billion miles KPBM) decreased by about $13 \%$ overall (Table 1.11). The trend in road kills (KPBM) has been a declining one as the deer population decreases. The KPBM rates over the last 5 years are similar to the levels reported in the early 1990s.

New spotlight routes were initiated in 2006 and replaced the old spotlight routes in 2012. The new routes consist of 199 transects distributed among all counties for a total survey mileage of about 4,750 miles; more than double the transect length of the old spotlight routes. The new spotlight survey transects are also set up to be more representative of the available rural habitats within a county. The average number of deer observed per 25 miles decreased by about $17 \%$ on the new routes in 2013 (Table 1.11) The new routes have lower variability than the old routes.

The bowhunter observation data, which began to be collected during the 2004 season, has replaced the aerial deer survey as a trend index. This survey represents over 100,000 hours of observation distributed throughout the state and is conducted voluntarily by a randomly selected group of Iowa archers. The tactics typically used during this season (stand hunting) make easier for hunters to gather observational data.

The estimated harvest from 20062013 was utilized in the population model and the resulting "best fit" simulation indicates a declining deer population statewide (Figure 1.7). The model suggests that about a $5 \%$ decline in the population occurred as a result of the 2013/14 harvest in conjunction with other mortality factors. The model has its best correlations with components of the road kill and bowhunter
observation data.
The data indicates that, statewide, the deer herd has been declining since 2006. All of Iowa's counties have reached or are close to the established goal.

## Outlook for 2014

After 10 years of increased doe harvest, hunters are seeing reduced deer numbers in most areas of the state. The goal is a stable population at a level comparable to the mid-to-late 1990s. A population at this level should sustain an estimated annual harvest of 100,000 to 120,000 deer.

Twenty seven counties, primarily in north-central and northwestern Iowa, are currently at or slightly below the department's goal. The regulations for 2014 restrict the harvest to antlered deer during the early muzzleloader and first shotgun seasons.

Dramatic reductions were made to the county antlerless quota $d$ for the 2014 season. The January antlerless season was also eliminated for the $2014 / 15$ season.

Hunters can drive deer numbers lower than desired in local areas. Hunters will still need to be judicious in their use of antlerless licenses or deer numbers may go below the department's goal. Conversely, there are areas in some counties that are at goal where deer numbers are still overabundant. Hunters need to work with landowners to find a desirable level of harvest.

Deer numbers are still higher than the department's goals in some areas however most of these areas are near urban areas, parks or private refuges and the special hunts and depredation licenses provide the best management opportunity to fine to the harvest in these areas.

Iowa experienced another outbreak of epizootic hemorrhagic disease (EHD) in 2013. The summer and fall of 2013 was abnormally hot and dry. Sick and dying deer began to be reported in August and reports continued on into November.

In 2013 there were 1,053 reported suspect cases of hemorrhagic disease in 54 Iowa Counties (Fig. 1.8). Tissue samples were collected from 6 deer across the state that had been dead for less than 24 hours and submitted to the Southeastern Cooperative Wildlife Disease Study lab for virus isolation. Virus isolates of EHDV-2 were detected in four of the samples. In the remaining two samples, EHDV and BTV were not detected.

The 2013/14 winter started very cold and got colder with above normal snowfall in northeast Iowa.

Figure 1.1 A comparison of the post-season harvest estimates from 1985-2005 (the top line) with the reported harvests from 2006-13 (the bottom line). The dotted line would be the "actual" harvest based on annual reporting compliance estimates (2006-13) and on 2006 reporting rates ( $90 \%$ ) for the years prior to 2006 (the first year of mandatory reporting).

Figure 1.2. The reported number of antlered bucks, does, and button bucks killed from 2006 2013

Figure 1.3 The number of paid resident antlerless-only license available in 2013/14 in each county. The shaded counties were open for the January antlerless-only season and centerfire rifles were legal during the season in the dark shaded counties.

Figure 1.4 The average number of deer killed per square mile in each county during the 2013/14 deer season using the reported harvest.

Figure 1.5 The proportion of the reported harvest that were does in each county during the 2013/14deer season.

Figure 1.6 The proportion of the total reported doe harvest in each county that were killed during the 2013/14 January Antlerless deer season.

Figure 1.7. A comparison of the results from the statewide population simulation with deer population trend surveys. This simulation uses the 2013 harvest from the reporting system and a reporting rate of $80 \%$.

Figure 1.8. The number of deer killed by hemorrhagic disease mortalities in each county in 2013.

Table 1.1 A summary of the number of licenses issued, hunters, reported harvest and success rates for the 2013-2014 season.

| Season | License Types |  | Licenses | Hunters | Does | Antlered | Buttons | Sheds | Success |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## WILD TURKEYS

## Historical Perspective

History: Iowa's primitive oak-hickory forests covered nearly 7 million acres ( 2.8 million ha) during the original land survey in 1859 (Thornton and Morgan 1959). Settlers' records indicate turkeys were associated with most of this timber. Although turkeys may not have been as numerous in Iowa as in their primary range east of the Mississippi River, they were still plentiful (Peterson 1943). Unfortunately, wild turkeys were eliminated from Iowa by the early 1900's due to habitat loss and partly because of uncontrolled subsistence market hunting (Little 1980).

Habitat: Only 2.6 million acres (1.1million ha) of forest remained when the second land survey was completed in 1956, a reduction of $63 \%$ in a century, and perhaps $50 \%$ of the remaining forest was badly mismanaged through overgrazing (Thornton and Morgan 1959). In 1974, Iowa had 1.6 million acres of forestland, which made up $4.3 \%$ of the State's land area. Iowa's forests now total 2.1 million acres ( $850,202 \mathrm{ha}$ ), just $5.7 \%$ of the State and only $30 \%$ of pre-settlement forests (Leatherberry et al. 1990). Forest types throughout Iowa are second or third growth oak-hickory on uplands and elm-ashcottonwood on floodplains (Ostrom 1976). Oak types constitute $55 \%$ of all forest stands, with red oak - white oak - hickory ( $35 \%$ of all forests) dominant in all regions. Maple/basswood stands (10\%) are found on mesic sites and are climax in the northeast and central regions, but are replaced by white oak ( $10 \%$ ) and short, scrubby bur oak ( $10 \%$ ) in the southern and arid western regions, respectively. Aspen and other northern
hardwoods (1\%) are found occasionally in the Northeast. Statewide, $65 \%$ of all commercial stands are entering sawtimber and $20 \%$ are in pole timber (Leatherberry et al. 1990). Ninety-two percent of Iowa's forest land is privately owned, with nearly half of the remaining $8 \%$ in state ownership, $38 \%$ owned by other public agencies and $14 \%$ in park-refuges withdrawn from active management (Ostrom 1976, Leatherberry et al. 1990). Iowa has no national forests, parks or wildlife refuges devoted to forest land management.

Restoration: The Iowa Department of Natural Resources (IDNR) began
experimenting with turkey restoration in 1920 using pen-reared birds. Releases were made over the next 18 years but all releases were uniform failures. The first attempts at releasing
transplanted wild turkeys were in the early 1960's. Rio Grande and Merriam's subspecies were released at several sites during the 1960's but ultimately their poor adaptation to Iowa's oak-hickory forest led to population failures for both subspecies. The first release of eastern wild turkeys was in 1966 in Lee County. The population response of these turkeys was phenomenal survival of released birds, reproduction, and poult survival were all excellent. The success of this eastern subspecies stocking led to an additional stocking that also proved successful. By 1971 it was obvious that the Eastern subspecies was the turkey to use in future restoration attempts.
Since the initial 1965 release, 3,578 Eastern wild turkeys have been trapped and released at 259 sites at a stocking rate of approximately 3 adult gobblers and 10 hens per site. Nearly all sites are considered successful. No sites are currently
considered to be unsuccessful. Most sites were opened to hunting after populations were established, usually about 5 years poststocking. Restorations by the IDNR during the last 2 decades have returned wild turkeys to about $95 \%$ of the remnant timber stands in the state. Restoration efforts ended in 2001 with the last release site occurring in Linn County.

## Spring Harvest Survey

History: Spring bearded-turkey-only hunting seasons began in 1974. The objective of Iowa's spring season has been to maximize hunting opportunity while maintaining a quality hunting experience. Quality hunting is defined as the chance to hunt turkeys reasonably free of interference from other hunters. The primary method used to reduce interference is to control hunter densities through license quotas established for multiple zones and seasons. Annual licenses issued, hunters, and harvest increased gradually from 1974-87 (Fig. 2.1). During 1988-99, there were dramatic increases in license issue and hunter numbers due to an unlimited license quota in the fourth season. The area open to spring turkey hunting in Iowa also increased dramatically from 2 small southern zones and 1 larger northeast zone in 1974 to the entire state during the 1999 spring season (Fig. 2.2, a and b). Hunter numbers and timber acres with huntable turkey populations have increased proportionally, allowing hunter densities to remain at $<4$ hunters/mi2 of timber per season. 2014: Iowa's 41st modern spring hunting season recorded an estimated 11,401 turkeys harvested, with 50,966 licenses sold (Table 2.1 and 2.3). This was the $26^{\text {th }}$ year the entire state was open to spring turkey hunting (Table 2.11). The 44-day season (5 April through 18 May, 2014) was partitioned into 5 separate seasons: a 9-day
youth-only season, and 4 regular seasons (4,5, 7, and 19-days). The 4 -season format, with unlimited license quota for all the periods, resulted in 44,545 resident shotgun licenses issued, which was an increase of 1,918 . An additional 6,421 archery-only licenses were issued in 2014. Archery-only licenses harvested 1,064 turkeys, resulting in a $16.6 \%$ success rate in 2014. Twenty-two percent of the resident hunters were successful in harvesting a gobbler in 2014 (Table 2.4). Spring harvest success rates fluctuated around 20-30\% during the first 12 years (unweighted average $=25.1$ for 1974-85) but success increased each year during 1985-88 (Fig. 2.4). Declines observed in spring hunter success rates during 1983 and 1984 can be partially explained by poor brood production during the summers of 1982 (Fig. 2.4). Similarly, the decline in hunter success rates between 1988 and 1993 may be explained by 6 years of poor brood production starting in 1988. The success rates from 2002-2006 averaged $46.0 \%$. The decrease in success rates beginning in 2007 and number of turkeys harvested is likely due the change in survey methods. In spring of 2007, mandatory harvest reporting required successful hunters to report turkey harvested. A follow-up post card survey for spring of 2007 revealed $74 \%$ compliance rate, which equated to nearly 4,000 harvested turkeys that were not reported initially during the spring season. The major reasons for the non-reports were attributed to hunters forgetting to report ( $40 \%$ ), difficulty in reporting process ( $29 \%$ ), and unaware of the requirement (22\%). This was the 25 th spring that nonresidents were allowed to hunt turkeys in Iowa. Quotas filled in zone 4 (seasons 2,4), zone 5 (seasons 3,4 ), zone 6 (season 4 ), and zone 8 (seasons 3,4) in 2014, leaving 265 licenses available. Non-resident hunters harvested 750 turkeys (Table 2.3). Nonresidents
reported a higher success rate for spring gobblers than did residents (39\% versus $22 \%$, respectively) (Table 2.4).

In spring of 2014, known jakes (spurs $<1 / 2$ ") harvested were $12 \%$ of the total harvest ( $20 \%$ the previous year). Turkeys harvested with spurs $1 / 2 "-3 / 4$ " were $27 \%$ ( $23 \%$ in 2013) of the total harvest. The majority (61\%) of turkeys harvested in 2014 had spurs greater than $3 / 4$ of an inch in length.

## Youth Turkey Season

Iowa's 10th youth spring turkey season has held in April 5-13, 2014. During the 9 day season, youth 15 and younger were allowed to participate with an accompanied licensed adult (adult licensed for one of the regular seasons). In 2005, the first year of the youth season, ages were limited to ages 12-15. Starting in 2006, ages 15 and younger could participate in the youth season. Youth season license sales increased by 996 for a record number $(5,035)$ of licenses sold (Fig. 2.8). Since the inception of ELSI (Electronic Licensing System of Iowa) in 2001, hunter age and gender has been recorded (Fig. 2.8). From 2001-2006, youth spring turkey hunters (age 15 and under) increased each year. After the first youth season in 2005, youth licenses have shown an overall upward trend. (Fig. 2.8). A code change in 2014 allowed for unfilled youth season tags to be valid for any other spring turkey season until filled.

## Fall Harvest Survey

History: Fall, any-sex turkey hunting was initiated in Iowa in 1981 to provide additional hunting recreation from the wild turkey resource. Because any-sex hunts are more controversial than male-only hunts and potential exists for over-harvesting hens, carefully controlled fall hunts began in 1981 on an experimental basis. These hunts
occurred in portions of southern Iowa, which had established, stable turkey populations. Fall turkey hunting has changed dramatically since the initial experimental 1981 season. The area encompassed by fall hunting zones has increased from 2 small zones in southern Iowa during 1981 to 6 zones in 2014 encompassing the entire state (Fig. 2.6, a and b). Fall zone boundaries in 1990 encompassed 9.7 times more area than in 1981, with 13.9 times more by 2005 (Table 2.12). Although zone boundaries did not change during 1991-1994, only zones 3 and 6 (northeast Iowa) had shotgun licenses available (residents only). The 5 remaining fall zones experienced 6 years of poor brood production and therefore did not have any licenses available. However in 1995, because of increased brood production in 1994, almost the entire state was opened to fall hunting. In 1999, the amount of land open to fall hunting increased slightly from 1998 with the addition of zone 8 (Fig. 2.6). Results from a radio-telemetry study in southern Iowa and computer modeling of southern Iowa turkey mortality and hatching data suggest as much as $10 \%$ of the population could be removed during fall hunting without reducing long-term turkey populations. Past seasons' harvest have not approached this theoretical value. The present management objective is to increase fall hunting opportunities and harvest. A harvest of fall turkeys similar to the number of spring gobblers harvested is the present goal. The number of fall licenses issued, hunter numbers and harvest increased steadily from 1981-89 (Fig. 2.7 and Tables 2.5-2.7). As with spring seasons, fall turkey hunters have previously had exceptional statewide success rates, averaging $51 \%$ during 1981-89 (Table 2.8). However fall success rates have had considerable annual variation, ranging from 40-60\% (Fig. 2.3). Fall license quotas generally surpassed
applications from 1981-84 and license quotas filled in only one zone in 1985. With the expansion of 2 hunting zones in 1986 a large increase in applications occurred. This resulted in rejecting a number of permit applications. License quota was increased in 1987 and in 1988. After 2 application periods in fall 1988, 51 licenses remained. Therefore license quota remained unchanged in 1989 although the hunting zone area increased (Table 2.12). Because of the documented poor poult production in 1988 and 1989, license quota remained unchanged for 1990. Fall 1990 hunting zones were expanded to distribute (and hopefully reduce) hunting pressure on flocks. Continued poor statewide brood production warranted dramatic reductions in fall harvest for 1991-1994. Only the northeast corner (Zones 3 \& 6) continued to have average brood production that allowed a fall shotgun season. Annual changes in hunter success, harvest and the age-sex composition of the fall harvest are at least partly explained by population events occurring in southern Iowa from 1981 to 1985. Excellent recruitment in the years of 1978 through 1980 produced very high turkey densities ( 100 wintering turkeys $/ \mathrm{mi} 2$ of forest on the southern Iowa Stephens Forest study area and region-wide densities of at least 40$50 / \mathrm{mi} 2$. A cool wet spring in 1981 led to essentially no recruitment just prior to the first fall season. A large carryover of adults from previous successful hatches meant that hunters had high success rates in the fall of 1981, but harvested almost no juvenile turkeys. A slightly better hatch in 1982, coupled with the reduction in available adult turkeys, led to proportionally more juveniles in the bag in 1982, but the harvest and success rates were reduced. A good hatch in 1983 produced more juveniles in the bag and an increased harvest, suggesting populations were recovering from a 2 -year depression. Another good hatch in 1984
resulted in even more juveniles in the bag and again an increased harvest. Fall 1985 was similar to 1984. The greatest effect was felt in southern Iowa where spring weather was least favorable in both 1981 and 1982. Indications of over-harvest on popular public hunting areas were greatest in the years when few juveniles were present to buffer adult turkey harvest. Harvest rates of adult hens ( $>2$ years old), the most important age class reproductively, were greatest when few juveniles were produced and decreased to tolerable levels when recruitment was good. A similar scenario developed during the recent 6-year (198893) decline in poult production. Climatic factors, i.e., 2 years of drought followed by floods in 1990, 1991, and 1993, are assumed responsible for the reduced poult production observed over that time period. Likewise, harvest and hunting success declined over the same period, presumably as a result of the decrease in poult production. Fall harvest and hunting success rate increased in 1995 following a slight increase in poult production in 1994. Harvest and hunter success increased slightly again in 1996 1999, but decreased slightly in $2000-2001$. However, fall harvest levels continue to be below the levels observed in the mid-1980's.

2013: Wild turkey brood production in 2013 decreased in Iowa compared to the previous year, with statistically significant decreases in poults per hen ratio. Hens with broods observed also decreased (Fig. 2.5) in many part of the state. Fall turkey hunter success rates remained similar in 2013 from 2012 (Table 2.8), but still well below the 2005 and prior estimates due to the change in harvest estimation (mandatory versus postcard survey as discussed earlier). Since the IDNR's main objective for wild turkeys is to maintain populations in all suitable habitats and provide high quality recreational
opportunity, a conservative fall turkey hunting season was established in 1992. Shotgun license quota was reduced from 7,600 licenses available in 1990 to only 1,530 in 1992, 1993, and 1994. An increase in poult production was observed in 1994, and shotgun license quota was increased in 1995 to 3,450 . Quotas were increased slightly again in 1996 to 3,850 , to 4,550 in 1997, to 5,650 in 1998 , to 6,225 in 1999. In 1999, zone 8 was created in north central Iowa and zone 6 was reduced east to Highway 63. All other zone boundaries remained the same as in 1998, and all zones had licenses available. In 2009, quotas were decreased. All zones except zone 8 \& 9 decreased (zone 4 from 4,500 to 1,500 , zone 5 from 700 to 650 , zone 6 from 3,000 to 1,400 , and zone 7 from 400 to 250 ). All fall licenses issued (Gun/bow and bow only) decreased in 2013 to 8,272 from 8,664 in 2012. Bow-only season started October 1 and ran until January $10^{\text {th }} 2014$ with December $7^{\text {th }}-22^{\text {nd }}$ excluded for the shotgun deer season. Gun/bow season was 54 days from October $15^{\text {th }}$ - December $6^{\text {th }}$ (Table 2.12). Thirty five percent of the fall licenses were issued free to landowners. Estimated numbers of active hunters were undeterminable since there was no post card survey after the season (mandatory reporting eliminated the post card survey). Only $8 \%$ of hunters reported harvesting a turkey, which was a large decrease from 2005, likely due to the mandatory reporting and low compliance rates (Table 2.8). Hunter success rates varied from $7.1 \%$ in zones 9 to $22.7 \%$ in Zone 8 (Table 2.8). Archery only licensed hunters reported a harvest of 123 turkeys in 2013 which was a decreased from the 2012 archery-only license harvest. The $5.5 \%$ success rate for 2013 archery only licenses was similar to the previous year's success rates for archery only hunters (Table 2.8). Nonresidents have not been permitted to hunt fall turkeys in Iowa since 1990.

Discussion: Fall turkey hunting techniques are sufficiently different from spring hunting so that past experience with spring hunting seems to have little impact on success in the fall. If anything, reliance on camouflage, sitting still, and calling (the basic spring hunting method) may be less successful and less utilized than walking and flushing turkeys in the small woodlot situations which comprise the bulk of Iowa turkey habitat. Even though fall shotgun success rates are quite high, fall turkey hunting has not been popular. It doesn't seem to appeal to spring hunters and hunter numbers seem to be more related to zone size than anything else. Fall archery hunting has even fewer devotees. In spite of these differences between spring and fall hunting, they have one important feature in common - hunter concentrations on public hunting areas. Hunter densities are much greater on public hunting areas than on private lands. By the nature of fall hunting this has less impact on perceived interference between hunters than it does in spring hunting. Crowding leads to lower success rates on public areas and, on the largest most popular areas, there are some indications of excessive harvest over theoretically desirable levels. Any area that the IDNR intends to manage for quality spring hunting may have to be zoned separately in the fall. Even in years of documented poor reproduction, hunters can still find turkeys due to Iowa's limited forest habitat and high turkey densities. Success rates are high for Iowa hunters when compared with surrounding states. Interference rates between hunters have not been documented in the fall since 1985. Interference rates have been lower during fall than in spring, which is probably due to the different techniques used for spring and fall hunting. Fall turkey hunter densities on public areas (that were surveyed) have been nearly 50 times greater than the average hunter density for private land. Turkey
harvest densities on 13 of 16 public areas surveyed equaled or exceeded the theoretical maximum allowable harvest of 2 turkeys $/ \mathrm{mi}^{2}$ of forest as determined from empirical population data gathered from Stephens State Forest (IDNR, unpubl. data). In 1986, only 4 counties sustained $>4$ hunters $/ \mathrm{mi} 2$ of forest, combined with turkey harvests of $>2 / \mathrm{mi} 2$ of forest. In 1987, with the large increase in licenses issued, 12 counties had both hunter densities $>4$, and turkey harvest $>2 / \mathrm{mi} 2$ of timber (out of 43 counties with reporting hunters). The high seasonal hunter densities were somewhat reduced by a 28 -day season during 1987. No more than $34 \%$ of the hunters and $39 \%$ of the eligible hunters (those who had not yet bagged a turkey) were afield on any day. The opening 2 days and 4 weekend days were the most popular hunting days. There were no evident relationships between daily hunting pressure and daily success rates. To reduce daily hunter densities, hunter interference rates and increase fall recreation days, the 1988 fall season was extended to 49 days (October 10 - November 27). However, a large increase in licenses issued in 1988 increased the number of counties exceeding allowable harvest and hunter density values to 16 (out of 53 counties with reported turkey harvest). Another record license issue in 1989 resulted in 24 counties (of 49 counties with reported turkey harvest) exceeding $>4$ hunters, and $>2$ turkeys harvested $/ \mathrm{mi} 2$ of timber. Fewer licenses were issued in 1990 and correspondingly only 16 counties exceeded hunter and harvest rate maximums. Due to continued poor brood production, both hunter numbers and harvest was dramatically reduced during 1991-1993 and increased only slightly throughout 1994-2000, but decreased slightly in 2001. Unfortunately, the present management concern is how to maintain turkey numbers instead of the enviable
situation of being concerned about hunter densities. The record number of active hunters in 2005 (since 1989) may be related to this being the first season that turkey hunters where allowed to use dogs. Likely, pheasant hunters took this opportunity to harvest turkeys opportunistically while pheasant hunting. With mandatory reporting system (initiated in 2006), active hunters numbers are undeterminable.

## Brood Survey

History: Information on annual variations in turkey productivity is needed to evaluate the status of turkey populations in various regions of the state. Because few reliable wild turkey census techniques have been developed, hunter success rates, turkey harvest levels, and age ratios of harvested birds are the best available indicators of relative turkey populations between hunting zones. Lewis (1975a, b) found significant correlations between both August poult:hen ratios, percent juveniles in the harvest, and total gobbler harvests in the subsequent spring in Missouri, suggesting that an index to productivity would be useful in establishing hunting regulations. Compared to the more formalized census procedures used for more visible wildlife species, indices to eastern wild turkey productivity are generally based on random observations of broods.

Methods: A list of cooperators has been established from IDNR personnel and rural residents living in selected portions of Iowa containing established turkey populations. All rural residents living in designated survey areas are sent a form to be returned if they are willing to participate in the survey. Each cooperator is sent a return-addressed postcards which are completed and returned based on turkey broods sighted between 1

July and 31 August. Productivity indices are constructed from these returns. Hanson (1988) compared the brood survey data with spring turkey harvest and data from a radiotelemetry study in southern Iowa. The poult: hen ratio (young/adult) was the variable that correlated best with the telemetry data. Results of additional analyses indicated that the brood survey did have some utility for forecasting turkey numbers available to the hunters in following springs. Additionally, Hanson concluded that in light of the correlations with harvest data the brood survey may also be useful for evaluating the status of turkey populations in various regions of the state. Survey statistics for 1976-2013 are summarized in Tables 2.9 and 2.10.

2013: Results from Iowa's 2013 summer wild turkey survey indicated a statewide decrease in turkey reproduction from the previous year (Tables 2.9 \& Table 2.10). In 2008, a new survey was developed that asked observers to also record toms seen, distinguishing them from hens. In previous years, observers were only asked to record hens observed. This may have influenced the percent of hens observed with broods (i.e. observers may have recorded toms as turkeys/hens without broods in the past). It is unlikely that all regions increased in the percent of hens observed with broods with the weather conditions of 2008 (extremely wet with severe flooding). Thus, any interpretation on the brood survey should be
limited to poults per hen and turkeys per flock in 2008. In 2009, the brood survey used new regions (Figure 2.5) to analyze the data. To allow comparisons between years, 2008 was also analyzed using the new regions (Tables 2.9 \& Table 2.10). Statewide, the average number of hens observed with a brood decreased by $13.7 \%$, while the average number of poults observed per hen decreased by $26.1 \%$ (Fig. 2.5) Regions 2,3 and 6 (north central, northeast and east central showed significant declines in the number of successful hens. Those same regions plus region 7 (Southwest Iowa) experienced statistically significant declines in the number of poults per hen. All other regions varied slightly from 2012 with no significant changes. South central Iowa continues on an upward trend (Fig.2.5).
Long range comparisons to previous years are difficult, since the survey methods changed in 2008, likely influencing the results in how the data was collected. The wet weather patterns in the spring and summer of 2013 likely impacted turkey reproduction throughout the state. May rainfall was 200-300\% above average throughout most of the state. Northwest Iowa experienced $200-400 \%$ increase in rainfall during the month of June. During June, the rest of the state had normal rainfall. Additional rainfall summaries are located at: http://www.ncdc.noaa.gov/temp-and-precip/maps.php

Table 2.3 Number of estimated spring turkeys harvested by zone, 1974-present.
Archery-only licenses not included from 1974-2006. Zone 5 was combined into Zone 4 in 1994.
Zones 1-3 were combined into Zone 4 in 2007.
In 2007, survey methods changed from a post-mailing survey to mandatory reporting, with an estimated $74 \%$ compliance rate.

## FURBEARERS

## Introduction

Iowa supports a wide diversity of native furbearer species including badger (Taxidea taxus), beaver (Castor canadensis), bobcat (Lynx rufus), coyote (Canis latrans), mink (Mustela vison), muskrat (Ondatra zibethicus), opossum (Didelphis virginiana), river otter (Lutra canadensis), raccoon (Procyon lotor), striped (Mephitis mephitis) and spotted (Spilogle putorius) skunk, red (Vulpes vulpes) and gray (Urocyon cinereoargenteus) fox, and weasel (Mustela spp.). Data regarding population trends for these species is important for effectively evaluating management efforts and the status of furbearer species, statewide. Longterm population data for many furbearer species is difficult to obtain and often lacking at a landscape-scale. However, data such as harvest, road-kill, the bowhunter survey, and spotlight survey indices have shown positive correlations with changes in population abundance for many of these species. The Iowa Department of Natural Resources (DNR) monitors population trends of Iowa furbearer species through the use of 1) annual furharvest reports, 2) April spotlight surveys, and 3) the Iowa Bowhunter Observation Survey.

Each year since 1930, the Iowa DNR collected harvest data for furbearer species from licensed fur dealers in Iowa. According to Iowa Code 109.97, every licensed fur dealer is required to report the total number of furs purchased per species from Iowa trappers and hunters by 15 May, annually. Although harvest data may only indicate a trend in population abundance, long-term harvest information provides a retrospective view of the status of various furbearer populations over time. Furthermore, in 1975, in response to debates regarding trapper verse hunter access to furbearer resources in the state, the Iowa DNR required licensed fur dealers to report the percent of raccoon, fox, and coyote pelts purchased from trappers and hunters, respectively. These data are useful in determining the impact of each harvest method on furbearer populations and the impact of weather on total harvest per species.

In 1978, the Iowa DNR began annual, statewide April spotlight surveys for raccoons and white-tailed deer (Odocoileus virginianus). Since 1978, the average raccoon harvest in Iowa has equaled or exceeded the average total harvest of all other furbearer species combined. Raccoon pelt values compose a significant portion of the total harvest value in Iowa each year. Thus, the April spotlight survey provides additional and useful data for managing this highly important furbearer species in the state.

Population trend data for furbearer species have also been gathered annually since 2004 through the Iowa Bowhunter Observation Survey. Avid archers were identified a priori for survey and provided
statewide observation data for Iowa furbearers during which more than 100,000 observation hours occur annually. Archers were considered ideal for collecting observation data because 1) avid archers may be considered experts at stand placement and concealment from wildlife, 2) avid archers are knowledgeable regarding species identification, 3) avid archers spend a great amount of time in-field each year, and 4) stand hunting methods for observing white-tailed deer lend well to observation of many furbearer species. Although this dataset is relatively new, it provides a repeatable and potentially long-term survey method for supplementing annual furharvest data.

## Historic Furbearer Harvest

Prior to the $20^{\text {th }}$ century, beaver furs were one of the most desired pelts on the market due to their thickness, durability, and warmth. However, because of high demand, beavers were overharvested around much of the world, even to extinction in Europe. In Iowa, beaver were extirpated by the turn of the century and populations were closed to harvest, statewide.

At the turn of the century, skunk furs were in high demand, worldwide. The fur trade was thriving as a result of increased visibility of actresses wearing furs and the high social status associated with fur products. However, in the 1930s, the market for skunk furs declined in response to demand for fox furs by the European fashion industry. During the 1930s, muskrat, mink, skunk, and opossum composed the largest proportion of total furbearer harvest in Iowa (Figure 3.1). By the end of the 1930s, the total skunk harvest in Iowa began to decline where as the red and gray fox harvests were growing.

In the 1930s and 1940s, the Iowa Conservation Commission (currently the Iowa DNR) initiated a beaver reintroduction program in Iowa. Beavers were live captured and transplanted throughout the state and by 1943, the harvest season for beaver was reopened. During the 1943-44 season, the total furharvest in the state reached an all-time high and 235 beavers were harvested (Table 3.4).

By the mid to late 1940s in Iowa, muskrat, mink, red and gray fox, striped and spotted skunk, opossum, coyote, and weasel harvests all faced dramatic declines in response to World War II (WWII). Within 5 years, total harvest collapsed from an alltime high of 418,484 to an all-time low of 135,108 . Twelve species composed the total harvests in the early 1940s but during the 1947-48 season, only muskrat, mink, striped and spotted skunk, red and gray fox, and raccoon were reported.

Following WWII, the fur market continued to depreciate as the production cost for labor-intensive fur products exceeded fur values and the need for fur products was replaced by the development of central heating. Society began viewing fur products as a trend characteristic of the previous generation and the demand for fox furs on the European market declined. Mink products, however, were viewed more favorably by the high class resulting in increased demand compared with previous decades.

Although demand was high, mink harvests in Iowa declined sharply in the early 1950s and remained low as a result of extended drought in the region and overall low mink prices, worldwide. Muskrat, striped and spotted skunk, red and gray fox, coyote, opossum, badger, and weasel also faced dramatic harvest crashes; composing less than $5 \%$ of the total harvest during the
decade. Ultimately, raccoon and muskrat harvests became more stabilized and composed the greatest proportion of the total harvest in the 1950s.

During the 1960s, total harvest increased and was relatively stable in Iowa. Beaver populations had continued to recover with steady harvests averaging 6,800 . Beginning in the early 1970s, raccoon, mink, red and gray fox, coyote, opossum, and badger all saw increased harvests. Striped skunk harvest had remained well below the 1930 average during the previous two decades but also showed stable, yet small recovery. By the 1979-80 season, record total harvests topped 1 million $(1,146,311)$ in Iowa for the first time in recorded history.

Although record furbearer harvests were achieved in the 1970s, spotted skunk populations struggled. Reports from the 1940s indicated that spotted skunk were common in portions of Iowa but by the 1970s, they were considered rare in the state. In 1976, the spotted skunk harvest season was closed, statewide, and the species was ultimately classified as an endangered species in Iowa. Throughout the 1970s and 1980s, the Iowa DNR received only 1 or 2 spotted skunk reports per year.

In the late 1970s and early 1980s, anti-furharvest groups formed and began protesting the development of fur products in the United States. Advertisements and celebrity endorsements were used to build public support against the fur trade. Demand for furs in North America subsequently declined although the fur market in Europe remained less affected.

Throughout the early and mid-1980s, total furharvest in Iowa remained relatively strong. However, by the late 1980s, Iowa experienced extreme drought conditions. When combined with a weak global fur
market, statewide harvests for all species crashed. Total reported harvest decreased by $450 \%$ in a 4 -year period; reaching as low as 216,874 by 1990-91 (Figure 3.2).

Total reported furharvest in Iowa remained low, stabilizing around 275,000 through the 1990s and early 2000s. Total harvest was primarily composed of raccoon and muskrat, as well as beaver, coyote, opossum, red fox, and mink in lower proportions (Figure 3.3). Harvest in the late 2000s steadily declined in response to 5 consecutive harsh winters. By 2010-11, harvest rebounded for all species except weasels (which had not composed a significant portion of the total harvest since the 1930s). Total reported furharvest during the 2010-11 season increased to 368,856 but remained below the long-term average $(457,878)$. In 2012-13, the total furharvest declined from the previous year $(365,395)$. For 2013-14, the total fur harvest in Iowa rose slightly $(380,720)$ even though the fur market sagged for some species later in the season (Table 3.4). A fairly strong fur market early in the season, rebounding raccoon numbers, and an increase in licensed fur harvesters likely contributed to the slight increase in harvest.

## Number of Licensed Furharvesters

The average number of licensed furharvesters in Iowa fluctuates with current fur markets. Generally, as fur prices increase, the number of furharvesters in the state increases in subsequent years, and vise versa (Figure 3.4). In 2013-14, the number of licensed furharvesters in Iowa reached another 10 -year high of 20,818 , which was up from 2012-13 $(19,268)$ (Table 3.2). This was likely in response to the increased fur market projections for the year, especially at the beginning of the furharvest season.

Over the past 10 years, the number of licensed fur dealers in Iowa has slightly decreased from 51 in 2001 to 41 in 2013 (Table 3.2). The number of licensed fur dealers appears to be less affected by the fur market but has shown signs it may stabilize or slightly increase the number of fur dealers in Iowa.

## Current Fur Market in Iowa

For the upcoming 2014-15 season, the fur market is less optimistic. The current fur market appears to be weakening after four years of continued growth. Demand is still primarily from Russia, China, and Korea, with several other smaller countries buying more fur. Fur market recovery has been slow, yet fairly steady and primarily limited by the European economy and the lack of a mass production capacity for fur products. High quality furs are still prized in the fashion/style industry. Overall, the market outlook is less positive in 2014. Raccoon pelt inventories are not cleared out and ranch mink values have fallen. Prices for wild muskrat, bobcat, mink, coyote, red fox, beaver, and otter are expected to remain somewhat decent in 2014. Muskrat prices should remain solid, although below those of other important species, it is still quite high for muskrat. Demand for striped skunk and weasel has slowly declined over recent years and may continue that trend in the following year.

In 2013-14, furbearer prices and number of pelts sold in Iowa followed current furbearer market trends. Average pelt prices increased for raccoon, muskrat, mink, beaver, coyote, red fox, opossum, badger, striped skunk, river otter, and weasel. Red fox and coyote average pelt prices increased the most in Iowa in 2013.

Gray fox and bobcat average pelt prices were down from the previous year
(Table 3.3). The total value for all species of pelts sold in Iowa did increase from the previous year $(\$ 6,034,386)$ (Table 3.1).
Mink, muskrat, raccoon, and red fox prices in 2013 were above the 5 -year and longterm averages (Table 3.1).

## 2013-14 Furharvest Season in Iowa

Annual and long-term weather events, habitat, and disease significantly impact furbearer populations and harvest success in Iowa. Precipitation, water levels in wetlands and waterways, and time of freeze all affect aquatic furbearer harvests especially and trapping effort throughout the state. Muskrat and beaver populations are cyclic and historically shown to fluctuate following wet/dry periods; resulting in fluctuating annual harvests.

Terrestrial furbearer (coyotes, fox, badger, etc.) harvests are impacted by the severity of winters, level of snow cover, and the duration of extreme temperatures because it effects daily animal movement. The severity of harsh winter weather has also been shown to limit hunter and trapper effort in some years. Typically, trapping and raccoon hunting success is greater during mild winters in which snow cover is minimal. Inversely, hunter success harvesting coyote and fox increases during years of extended snow cover. Ultimately, consideration of annual weather is important for analyzing harvest trends and developing sound management strategies for furbearers in Iowa.

The weather for furharvesters during the Fall and Winter of 2013-14 can best be described as challenging. Conditions were generally dry heading into November, especially southwest Iowa. The weather
during November was windy and wet at times for many parts of the state. Most of the state received very cold temperatures by the last week of November. By early December, many waterbodies of the state were frozen over. Statewide snowfall this past winter was about 36 inches. The western third of Iowa saw below normal snowfall while the eastern two thirds of Iowa saw snowfall 50-90\% above normal.

With the fairly dry conditions going into November during the 2013 furharvest season, it resulted in fair to poor furbearer trapping conditions statewide for aquatic species especially. A hard freeze-up and cold weather then reduced trapping effort in December and January

The gray fox harvest (16) for 201314 was under 100 again for the $5^{\text {th }}$ straight year which is cause for concern about their population level statewide (Table 3.4). Regional (Midwest) research has been initiated on this matter to help answer questions. The proportion of pelts purchased by Iowa fur dealers from trappers was higher than those harvested by hunters for raccoon and fox, however hunters harvested slightly more coyotes than did trappers in 2013-14 (Table 3.5). The total number of coyotes harvested increased from the previous year and doubled from just two years prior. A rise in the coyote population coupled with cold weather and snow cover made for more favorable hunting conditions for coyote than mild winter conditions. This likely resulted in the higher harvest for 2013-14.

The following sections cover 2013 harvest and populations trends for each specific furbearer species

## Raccoon

Raccoon harvest in the 1930s was relatively low and comprised only $3 \%$ of the total harvest (Figure 3.6). By the mid to late 1940s, raccoon harvests had tripled; comprising a significant portion of the total harvest (14\%) for the first time. Harvests steadily increased throughout the next two decades but remained relatively low until the early 1970s. During the 1970-71 season, raccoon harvest totaled approximately 94,000 . By 1974, raccoon harvests had boomed, experiencing a $300 \%$ increase to 292,064 . Although harvests had climbed to nearly 100,000 during the previous 2 decades, populations were steadily increasing. Corn was being planted on more and more acres creating an abundant food source. High harvest rates likely minimized disease outbreaks such as distemper, helping to maintain healthy populations as well. By the 1986-87 season, harvests reached a current, all-time high of 390,773 . However, within 3 years, harvests crashed to 103,468 (a $378 \%$ decline) as a result of poor market prices and regional drought. Average harvest throughout the 1990s and mid-2000s remained around 129,000. In 2010-2011, harvests again peaked to 236,943 , well above the 5 -year $(189,344)$ and long-term $(122,395)$ averages.

In 2013-14, the statewide harvest for raccoons was 308,025 . So it increased slightly from the previous year's harvest of 303,496 (Table 3.4). Trapping and hunting season dates ( 2 Nov-31 Jan), daily bag limits (no limit), and possession limits (no limit) remained the same (Table 3.6). The average raccoon pelt price in Iowa was $\$ 15.85$ ( $\$ 7.90-17.85$ ), which was higher than the 2012-13 price ( $\$ 13.60$; Figure 3.7 ; Table 3.3). Trapping accounted for $73 \%$ of the total harvest, up slightly from the previous
season. Coon hunting accounted for $27 \%$ of the total harvest (Table 3.5).

The 2013 Iowa Bowhunter Observation Survey indicated that statewide populations declined slightly (western Iowa) or remained stable throughout many regions of the state from the previous two years. However, this survey showed slight increases in south central and eastern regions of the state (Figure 3.8). Yet the 2013 April spotlight surveys indicated the overall statewide populations have slightly increased from the previous year and exceeded the 5-year average (Figure 3.9; Table 3.7). However, county by county April 2013 spotlight surveys also showed results varied with declines primarily from the previous year in central and north-central Iowa (Figures 4.0 and 4.1). This correlated with several field reports from those regions of Iowa of distemper outbreaks the previous Fall. Data from the spring 2014 spotlight survey is still being worked on and therefore not included here. Preliminary results from that survey indicate an increase in raccoons. Coon numbers in most regions are expected to rebound this upcoming year.

## Muskrat

Since the 1930s, muskrat consistently composed the greatest proportion of the total annual harvest in Iowa. Average pelt prices have remained consistently low compared with species such as raccoon, mink, and red fox (Table 3.1). However, because of the high muskrat population in the state and high rate of harvest over time, muskrat furs averaged $25 \%$ of the total harvest value in recorded history.

Fluctuations in the total annual furbearer harvest have primarily been due to the cyclic behavior of muskrat populations
(Figure 3.2). Historic muskrat populations in Iowa fluctuated greatly following wet and dry periods. Droughts in the 1930s, 1950s, and late 1980 s suppressed muskrat populations in the state. However, in subsequent wet years, populations quickly rebounded due to the prolific reproductive capacity of the species.

In 1979-80, muskrat harvest in Iowa reached a current, all-time high of 741,403 (Figure 4.2). Harvests varied throughout the early and mid-1980s but by the 1987-88 season, extreme drought, poor wetland conditions, and a suppressed fur market resulted in significantly depressed populations and a 30-year-low harvest. Excessive precipitation and flooding in 1993 improved habitat and by the mid-1990s, populations had steadily rebounded. In the late 1990s, wetland conditions began to deteriorate as increasing/stable, high water levels degraded marsh vegetation and habitat. Harvests again declined to pre-1993 levels and remained low; averaging 68,500 through the 2000s. In 2010-11, the muskrat harvest reached a decade high of 98,079 , yet still remained well below the long term average.

In 2013-14, the muskrat harvest was 30,584, which was a decrease from the previous season (Table 3.4). The last time a statewide harvest was lower than this was in 1947-48 (Figure 4.2). The pelt price for muskrats continues to remain high. With harvest being low, it certainly indicates a lowered trend in the muskrat population (Figure 4.3). Drought conditions in 2011 thru 2012 significantly decreased water levels in wetlands and subsequently suppressed muskrat populations and total harvest. There is concern whether other environmental factors are suppressing the muskrat population as well. Trapping season dates (2 Nov-31 Jan), daily bag limits (no
limit), and possession limits (no limit) remained similar to those in 2012-13 (Table 3.6). For 2013-14, the average muskrat pelt price in Iowa was $\$ 9.28$ ( $\$ 5.00-14.41$ ), which was higher than the 2012-13 price (\$7.48; Figure 4.3; Table 3.3).

Excessive statewide drought during 2012 was largely eliminated in the spring 2013 by heavy rains which filled or flooded several waterbodies throughout the entire state. However, by late summer 2013, most wetlands and marshes had again experienced low or completely dry conditions, creating unfavorable trapping conditions in 2013. It is unknown at this time whether muskrat populations will bounce back or increase with the generally wetter weather conditions occurring in 2014. This concern is not unique to Iowa, further studies of muskrats will likely be underway in the Midwest.

## Coyote

Coyote harvest in the 1930s was nearly non-existent in Iowa and totaled only 517 animals throughout the entire decade (Figure 4.4). Harvests increased in the 1940s and averaged 374 per year, but by the 1950s, had once again dropped off. Through the 1950s and 1960s, harvests averaged fewer than 75 animals per year with annual harvests as low as 10 per year. Beginning in the 1968-69 season, coyote harvests boomed and by 1976-77, reached a current, all-time high of 12,226 . Since the late 1970s, harvests have steadily decreased in the state but remained high in comparison to previous decades. Except for a dramatic decline in the late 1980s, harvests through the late 2000s averaged 6,800 , well above the long-term average $(4,207)$ (Figure 4.4). In 2009-10, harvests dipped below the longterm average but quickly rebounded to a 7 -
year high of 8,089 during the 2010-11 season.

In 2013-14, the coyote harvest was 15,347, which was a significant increase from the previous season and well above recent and long-term averages (Table 3.4). In fact, it's the highest harvest ever recorded for Iowa. The regular trapping and hunting season dates (2 Nov-31 Jan), daily bag limits (no limit), and possession limits (no limit) remained similar to those in 2012-13 (Table 3.6) with the coyote season open year round. The average coyote pelt price in Iowa was $\$ 23.92$ (\$6.80 - 41.00), which was also higher than the 2012-13 price ( $\$ 15.93$; Table 3.3). Trapping accounted for $47 \%$ of the total harvest which was the same as the previous season (Table 3.5). Hunting accounted for $53 \%$ of the total harvest. Ideal hunting conditions mainly occurred in January and February with significant snowfall to portions of the state.

The Iowa Bowhunter Observation Survey indicated the statewide population trended upward in 2012, especially throughout central and western regions of the state, and remained relatively stable in eastern portions of the state (Figure 4.5). Statewide, coyote populations from 2010 to 2012 appear to be remaining quite high for many regions of the state, especially the southwest. In 2013, this survey showed a slight downward trend in the coyote population. In 2012, there was a slight increase in the number of reports from the public of emboldened coyotes trailing joggers or harassing pets, however in 2013, we received far fewer of those reports.

## Red Fox

Red fox harvests through the mid1940s averaged approximately 6,900 in Iowa (Figure 4.6). Steady declines
throughout the late 1940s and 1950s resulted in an all-time low harvest of 1,147 during the 1958-59 season. Harvest numbers rebounded in the 1960s and in the 1968-69 season, reached a current, all-time high of 27,661. Harvests fluctuated sharply throughout the next two decades but remained high, averaging 19,000 through the mid-1980s. In the late 1980 s , red fox harvests began a steady declined and since the 2004-05 season, remained below the long-term average of 10,631 .

In addition to depressed fur markets in the 1980s, recent red fox population declines in Iowa have been attributed to two occurrences. Since the early 1980s, mange has remained persistent in red fox populations and suppressed population recovery in the state. Furthermore, high coyote populations have resulted in encroachment on areas historically considered red fox habitat, increased competition for food and den sites, and increased predation by coyotes.

In 2013-14, the red fox harvest was 4,099 , which was nearly identical from the previous season (Table 3.4). The 2013-14 harvest was just above the 5 -year average but below the long-term average. Trapping and hunting season dates (2 Nov-31 Jan), daily bag limits (no limit), and possession limits (no limit) remained similar to those in 2011-12 (Table 3.6). The average red fox pelt price in Iowa was $\$ 36.27$ ( $\$ 15.00$ 50.00), which was higher than the 2012-13 price ( $\$ 25.85$; Table 3.3). The average pelt price increased again last year and with the harvest staying about the same, indicates the fox population remained similar (Figure 4.8). Trapping accounted for $82 \%$ of the total harvest (red and gray fox), which was a slight increase from the previous season (Table 3.5). Hunting accounted for $18 \%$ of the total harvest (red and gray fox).

The 2013 Iowa Bowhunter Observation Survey indicated that population trends throughout most regions of the state were similar to previous years and still at relatively low numbers since 2004 (Figure 4.8). The population trend in southeast Iowa has decreased since the mid2000s.

## Gray Fox

Gray fox harvests in Iowa have followed similar trends to those of red fox, although historically, populations have existed at significantly lower numbers (Figure 4.9). During the 1930s and 1940s, harvests averaged around 1,300 . Gray fox harvests dropped below 1,000 in the late 1940s and remained low until the early 1970s. Harvests steadily increased and during the 1979-80 season, reached a current, all-time high of 3,093 . Whereas red fox harvests remained high throughout the 1980s, gray fox harvests have since dramatically declined. Since 1996-97, gray fox harvests have remained below their long-term average of 866. In 2009-10, gray fox harvests reached an all-time low of 13 in Iowa (Table 3.4).

In 2013-14, the gray fox harvest was 16, which was lower than the previous season's harvest and below the recent and long-term averages (Table 3.4). Trapping and hunting season dates ( $2 \mathrm{Nov-31}$ Jan), daily bag limits (no limit), and possession limits (no limit) remained similar to those in 2012-13 (Table 3.6). The average gray fox pelt price in Iowa was $\$ 16.81$ ( $\$ 10.00$ 26.44), which was lower than the 2012-13 price ( $\$ 27.01$; Table 3.3). Trapping accounted for $82 \%$ of the total harvest (red and gray fox), which was similar from the previous season (Table 3.5). Hunting accounted for $18 \%$ of the total harvest (red
and gray fox), which was similar from the previous season.

The 2012 Iowa Bowhunter Observation Survey indicated that populations in northern and central Iowa have remained stable but at relatively low numbers since 2004 (Figure 5.0). Observations in southeast Iowa showed trends similar to those of red fox and indicated that the population trend has remained low since the mid-2000s. Statewide, gray fox populations appear to be quite low in all other regions in 2013. Recent research has been initiated in the Midwest to study the factors for the dramatic decline in gray fox numbers.

## Beaver

By the early $20^{\text {th }}$ century, beaver were extirpated from Iowa. Harvests seasons remained closed throughout the 1930s and early 1940s while a statewide translocation and reintroduction program occurred. In 1943, the beaver harvest season was reopened and 235 were harvested (Figure 5.1). Beaver harvests averaged 450 through the late 1940s and by the early 1950s, began a steady upward trend. Harvests reached a current, all-time high of 18,459 during the 1988-89 season. Harvests declined in the early 1990s although quickly stabilized, averaging 10,800 through the early 2000s. Harvests progressively declined in the 2000s and dropped below the long-term average $(7,085)$ during the 2004-05 and 2006-07 through 2010-11 seasons.

In 2012-13, the beaver harvest reached an 19-year high of 15,457 ; a number similar to the high harvests recorded during the 1980s (Table 3.4). The harvest in 201314 declined to 7,496 . Trapping season dates were were similar to the previous year, with
the season extended two weeks in April (2 Nov-15 Apr) and daily bag (no limit) and possession (no limit) limits remained unchanged from 2011-12 (Table 3.6).

The beaver trapping season was extended from April $1^{\text {st }}$ back to April $15^{\text {th }}$ in the spring of 2012. The 2013-14 average beaver pelt price in Iowa was $\$ 16.01$ ( $\$ 4.00-$ 25.00), which was higher than the 2012-13 price (\$13.66; Table 3.3).

## Mink

The proportion of mink in the total Iowa fur harvest has remained relatively constant since the 1930s (Figure 3.2). Mink harvests reached a current, all-time high of 60,397 during the 1946-47 season as a result of a sudden increase in value from the previous season ( $\$ 6.75$ to $\$ 28.16$ per pelt). During World War II, European demand for furs collapsed and within 2 seasons, Iowa mink harvests dramatically fell to 16,571 . Mink harvests stabilized in the early 1950s and averaged around 16,000 through the next 4 decades. Since the mid-1990s, mink harvests have remained below the long-term average. Harvests in the early and mid2000s showed a steady decline although in 2010-11, topped the 5- and 10-year averages at 11,262 (Figure 5.2).

The 2013-14 mink harvest was 5,582 which is a decrease from the previous season (Table 3.4). The 2013-14 harvest was below the $5-$ and 10 -year averages, and well below the long-term average (Figure 5.2). Dry weather conditions and a hard freeze-up were likely the main reason for the lower harvest for mink. Disease threats to wild mink is another factor that may impact the mink population negatively, but the extent of that impact is unknown at this time. The trapping season dates ( 2 Nov-31 Jan) and daily bag (no limit) and possession
(no limit) limits remained similar to those in 2012-13 (Table 3.6). The average mink pelt price in Iowa was $\$ 16.50$ ( $\$ 7.00-21.10$ ) in 2013-14, which was higher than the 2012-13 price (\$15.91; Figure 5.3; Table 3.3).

## Opossum

During the 1933-34 harvest season, the opossum harvest reached a current, alltime high of 83,625 (Figure 5.4). In the preceding and following years, harvests more typically averaged around 30,000 . In the late 1940s, harvests significantly declined, reaching an all-time low of 953 in 1958-59. Opossum harvests remained below 10,000 until the early 1970s, when harvests again reached numbers comparable to those seen in the mid-1940s. In the late 1980s, harvests decreased again and have remained below the long-term average $(14,549)$ from the 1990 s to present.

The 2013-14 opossum harvest was 5,668 , which was a slight increase from the previous season (Table 3.4). The 2013-14 harvest was above the 5 - and 10-year averages but below the long-term average. Trapping season dates (2 Nov-31 Jan), daily bag limits (no limit), and possession limits (no limit) remained similar to those in 201213 (Table 3.6). The average opossum pelt price in Iowa was $\$ 2.00$ ( $\$ 0.25-4.00$ ), which was slightly higher than the 2012-13 price (\$1.25; Table 3.3).

The 2013 Iowa Bowhunter Observation Survey indicated the population is trending upward in almost all regions of Iowa (Figure 5.5).

## Badger

Although an all-time low badger harvest occurred in 1932-33 (17), stable harvests averaging 450 per year were
recorded from the mid-1930s until the mid1940s (Figure 5.6). Harvests declined in subsequent years and averaged below 100 throughout the 1950 s . By the late 1960s, badger harvests reached levels comparable to those recorded in the early 1940s. In the 1970s, harvest rates boomed in Iowa, reaching an all-time high of 3,274 during the 1979-80 season. Harvests remained high throughout the 1980s but ultimately crashed to below 500 by the early 1990s. Harvests fluctuated around the long-term average (670) throughout the 1990s and 2000s.

In 2013-14, the badger harvest was 1,006 which is down slightly from the previous year (Table 3.4). The 2013-14 harvest was again above recent and longterm averages for Iowa. Trapping season dates ( 2 Nov-31 Jan), daily bag limits (no limit), and possession limits (no limit) remained similar to those in 2012-13 (Table 3.6). For 2013-14, the average badger pelt price in Iowa was $\$ 17.14$ ( $\$ 5.00-24.00$ ), which was slightly higher than the 2012-13 price (\$15.24; Table 3.3).

The 2013 Iowa Bowhunter Observation Survey indicated that populations have remained fairly stable throughout most of the eastern portions of the state (Figure 5.7). The population trend in central and western Iowa shows a decline. Populations in western Iowa have typically remained a little higher than the remainder of the state.

## Spotted Skunk

Spotted skunk (also called civet cat) was proportionally one of the top 4 most harvested furbearer species throughout the 1930s in Iowa. In 1933-34, an all-time record 88,532 were harvested (Table 3.4). In 1946-47, the spotted skunk harvest crashed, although similar trends were
recorded for most furbearer species in the state (Figure 5.8). Harvests stabilized around 1,700 in the 1950s and remained low throughout the decade. Many furbearer species began to show improvements in harvest numbers by the mid-1960s, but spotted skunk populations began a further decline. In 1976, the spotted skunk harvest season was closed and the species was classified as an endangered species in Iowa. During the 1970s and 1980s, 1-2 spotted skunk sightings were reported to the Iowa DNR per year. Since 1992, the only reported sighting in the state was a road kill individual in Ringgold County in southwest Iowa. Currently, spotted skunk are likely extirpated from the state. This is likely due to habitat changes and changes in farming practices. We do get an occasional report of one in southern Iowa, but have not been able to verify any of them to this point.

## Striped Skunk

Striped skunk was proportionally the second most harvested furbearer species during the 1930s in Iowa (Figure 3.1). In 1936-37, an all-time record harvest of 153,497 was reported, although over the subsequent decade, harvest numbers for striped skunk steadily declined (Figure 5.9). By the early 1950s, harvests dropped below 10,000 and have generally averaged below 1,000 since 2008-09.

In 2013-14, the striped skunk harvest was 779 , which was similar to the previous season (Table 3.4). The 2013-14 harvest was slightly above the 5 -year average (704) and significantly below the long-term average. Trapping season dates (3 Nov-31 Jan), daily bag limits (no limit), and possession limits (no limit) remained similar to those in 2012-13 (Table 3.6). The average striped skunk pelt price in 2013-14
for Iowa was $\$ 4.43$ (\$0.50-6.00), which was up slightly from the 2012-13 price ( $\$ 2.20$; Table 3.3).

The 2013 Iowa Bowhunter Observation Survey indicated the population trend declined slightly throughout all regions of the state (Figure 6.0). Populations have been high in western and south-central portions of the state and relatively lower in central and eastern portions since the mid-2000s. Although the observation survey indicates that decent numbers exist in Iowa, low market prices for skunk furs likely have kept harvest relatively low in comparison to species (e.g., badger) which remain at low population numbers yet produce relatively high harvests due to good fur prices.

## Weasel

Weasel harvests during the 1930s and 1940s were characterized by dramatic fluctuations (Figure 6.1). In 1936-37, just 4 years following a decade low harvest of 256 , weasel harvests reached a current, all-time high of 7,190 . Harvests averaged 4,400 in the early and mid-1940s but by the mid1950s, had dropped below 500 per year. Weasel harvests steadily decreased during the next 3 decades and in 1976, the harvest season was closed in Iowa. In 1987, the weasel harvest season was once again reopened, although the first reported harvested weasels did not occur until 200910. Harvests in 2009-10 and 2010-11 were 56 and 7, respectively, characteristic of the low harvests numbers reported throughout the 1960s and 1970s.

In 2013-14, the reported weasel harvest was 9 animals (Table 3.4). Although in should be noted that trappers keep at least some of their weasel pelts and don't sell them. Trapping season dates (2

Nov-31 Jan) and daily bag (no limit) and possession (no limit) limits remained similar to those in 2012-13 (Table 3.6). The average weasel pelt price in 2013-14 for Iowa was $\$ 2.46$ (\$2.14-4.00), which was a bit higher than the 2012-13 price ( $\$ 2.12$; Table 3.3).

Low harvest numbers may indicate that statewide populations have not recovered since the 1970s. However, it is likely that trappers have not yet targeted the species to any great extent since the harvest season was reopened in 1988 due to the low value of weasel pelts.

## River Otter

Except for small remnant populations along the Mississippi River, the river otter was extirpated from Iowa by the early $20^{\text {th }}$ century. In 1985, the Iowa DNR initiated a reintroduction program in which 16 otters were released at Red Rock Reservoir in Marion County. Due to state regulations, the Iowa DNR was not able to directly purchase otters from Louisiana. A compromise was reached between Iowa, Kentucky, and Louisiana in which Kentucky purchased the otters from Louisiana ( $\$ 400 /$ otter) and Iowa traded wild turkeys to Kentucky (2 turkeys/otter) in exchange for the otters.

Between 1985 and 2003, a total of 345 otters were released throughout the state. By 2006, otter populations had expanded statewide. The Iowa DNR created the first regulated otter trapping season in 2006. The harvest quota was set at 400 animals (limit of 2 per licensed furharvester) and a 72 -hour reporting grace period was established until the quota was met (Table 3.8). The 2006 harvest exceeded the quota by 66 otters so in 2007, the reporting grace period was shortened to 24 hours. The
shortened grace period proved effective as the 2007 harvest exceeded the quota by only 16 animals. Harvest quotas were increased to 500 for the 2008,2009 , and 2010 seasons with harvests totaling 495,519 , and 515 per year, respectively.

In 2011, the harvest quota was set at 650 with a limit of 3 otters per licensed furharvester. A total of 770 otters were harvested ( 28 from unknown sources) which exceeded the quota due to inconsistencies in harvest reporting among individuals (Figure 6.2).

For 2012, the otter harvest quota was increased to 850. A total of 974 otters were harvested.

For the 2013-14 trapping season, the otter harvest quota was lifted for the first time; however the bag limit was reduced from 3 otters down to 2 otters per trapper. The 2013-14 otter harvest was 1,165. County by county harvest is documented through CITES tag reports which shows the highest otter harvests again occurred in eastern Iowa (Figure 6.2).

The average otter pelt price in 201314 for Iowa was $\$ 58.26$ ( $\$ 35.00-80.00$ ), which was slightly higher than the 2012-13 price (\$56.71; Table 3.3).

Since the trapping season was established in 2006, the sex ratio of harvested otters has remained relatively even (Figure 6.3). Foothold traps, conibear traps, and snares were the most common harvest method in the state (Figure 6.4; Table 3.9). The number of furharvesters intentionally targeting otters has remained relatively low as incidental captures appear to be the most common cause for capture in Iowa (Figure 6.5). Although the harvest season has been highly successful and the fur market for otter pelts is strong, the number of furharvesters intentionally
targeting otters has has only increased slightly since 2006 (Figure 6.6).

The Iowa Bowhunter Observation Survey is somewhat useful for otters, but not as much (correlated) as it is for other upland furbearer species that are more readily viewed by bowhunters. The 2013 bowhunter survey indicated that population trends were variable among regions - some up, some down (Figure 6.7). Harvest data and bowhunter observations suggest that 2013 regional populations were highest in north central and south central Iowa, although strong harvests numbers were also reported in counties containing the Iowa River Corridor (Figure 6.2).

Despite exceeding quotas in 6 of the previous 7 seasons, our data indicates that otter populations appear to be quite variable from region to region throughout Iowa, but generally doing very well. With the harvest quota being lifted in 2013, but the limit reduced from 3 otters per licensed trapper down 2 otters, the harvest was only slightly higher than the previous year with a harvest quota in place. At this time, the trapping regulations in place for the otter harvest are reasonable. However if data indicates the otter population is trending steadily downward; then the more restrictive harvest quotas will be implemented again.

## Bobcat

Three felid species including bobcat, Canada lynx, and mountain lion were native to Iowa, although historically, bobcats were most common. By the 1930s, only small remnant populations of bobcat remained scattered throughout the state, particularly in northeast Iowa. Between the 1940s and 1980s, bobcat sightings were exceedingly rare and the species was likely nearly extirpated for extended periods.

Since the early 1990s, bobcat sightings, road kills, and incidental captures by trappers had progressively increased in Iowa. By the early 2000s, confirmed bobcat sightings were recorded in 44 counties, primarily in southern Iowa and along the Mississippi and Missouri River. Populations were naturally expanding in Iowa, which was similarly being documented in Missouri, Nebraska, and Kansas. In 2003, the Iowa DNR concluded that populations had steadily increased and stabilized; therefore bobcats were delisted as a threatened species in the state. Over the next 2 years, bobcat sightings continued to increase. By 2005, confirmed sightings had been recorded in 78 counties.

In 2007 , the Iowa DNR created the first regulated bobcat harvest season in the state. The harvest quota was set at 150 animals (limit of 1 per licensed furharvester) and a 24 -hour reporting grace period was established until the quota was met (Table 4.0). Bobcat harvest was limited to the bottom two tiers of counties in Iowa (21 counties). The 2007 harvest included 149 bobcats plus an additional 5 road kill individuals.

Harvest quotas were increased to 200 bobcats during the 2008 and 2009 seasons with harvests totaling 232 and 231, respectively. Woodbury, Monona, Harrison, and Pottawattamie counties along the Missouri river were added to the open zone. In 2010, harvest quotas were further increased to 250 and a total of 263 bobcats were reported. The 2010 open zone was expanded to include the bottom 3 tiers of counties in Iowa plus Guthrie County in south-central Iowa. In 2011, the harvest quota was set at 350 (limit of 1 per licensed furharvester) and the open harvest zone remained similar to the 2010 zone (Figure $6.8)$.

In 2012, the harvest quota was set at 450. The bobcat harvest in 2012 was 528 (Table 4.0).

The bobcat harvest quota was lifted for the first time in the 2013-14 fur season; as it was for otters also. The 2013-14 harvest for bobcats was 978 (Table 4.0).

The average bobcat pelt price in Iowa for 2013 was $\$ 79.20(\$ 10.00-115.50)$, which was lower than the 2012-13 price ( $\$ 83.89$ ) but still the highest average value per pelt of all Iowa furbearer species (Table 3.3). Harvest was highest mainly in the south central region of Iowa (Figure 6.9). Despite the season being open 89 days in 2013-14, the highest rate of harvest occurred in November and decreased in December and January with the most harvest occurring on weekends and holidays (Figure 6.9). Only 37 bobcats were harvested by gun deer hunters, which was fewer than expected.

Since the bobcat harvest season was established in 2007, the sex ratio of harvested bobcats has remained relatively even (Figure 7.0). Snares, conibear traps, and foothold traps were the most common trapping method and archery the most common hunting method in the state (Figure 7.1; Table 4.1). The number of furharvesters intentionally targeting bobcats has remained lower than those trapped incidentally. Incidental captures are still the more common cause for capture in Iowa (Figure 7.2). Although the harvest season has been highly successful, and the fur market for bobcat pelts is strong, the number of furharvesters intentionally targeting bobcats has remained relatively constant since 2006 (Figure 7.3).

The 2013 Iowa Bowhunter Observation Survey indicated that since regulated bobcat trapping began in 2007, populations have remained fairly stable
throughout the state, with nearly all regions of the state showing a slight trend upward in 2013 (Figure 7.4). Regional population trends are highest throughout southern Iowa. This is consistent with data documented from harvest, road kills, incidental trapping captures, and habitat modeling. Populations appear higher in west-central Iowa along the Missouri River which is further supported by good harvest numbers in Monona and Harrison counties. Recovery in central and northern Iowa has been slow but fairly consistent. Lower numbers of bobcats in these regions of Iowa is mainly due to a lack of ideal habitat when compared with southern Iowa.

Despite exceeding quotas in 5 of the previous 6 seasons, bobcat populations have remained good throughout the state where ideal habitat exists. For 2014-15, the bobcat harvest season will remain the same as it was for the 2013-14 season, no quota and the limit remaining at 1 bobcat per licensed furharvester. The 2014-15 harvest season will be open with the regular fur harvest season (1 Nov-31 Jan).

${ }^{1}$ Long-term data dates back to 1930.
${ }^{\text {a }}$ For furharvesters which reported number of pelts purchased without average price paid per pelt, total values for those furharvesters were estimated using the overall average price paid per pelt calculated from all furharvesters (e.g., two furharvesters reported purchasing 37 total red fox pelts but did not report the average price paid per pelt. Those 37 pelts were multiplied by the average price of $\$ 17.74$ for estimating total values for those furharvesters).

Harvest data excludes known road-killed otters.
a First regulated otter harvest season in lowa.
Season bag limit of two per licensed furharvester.
Season bag limit of three per licensed furharvester.
Harvest data includes animals harvested during a 72-hour grace period following season closure.
Harvest data includes animals harvested during a 48-hour grace period following season closure.
Statewide includes 99 lowa counties.

Data includes harvest from unknown sources; may include road-killed animals. Source of collection was not specified in some harvest reports.

# Waterfowl Management, Seasons, and Harvests in Iowa 

Figures and Tables referenced in this document are separate .pdf files.

## Duck Breeding Populations

Breeding population estimates are made each year for 10 key species of ducks in the principal breeding areas of Alaska, Canada, and the northcentral United States (Table 4.1, Fig. 4.1). Surveys are conducted in May and early June by the U.S. Fish and Wildlife Service (USFWS), Canadian Wildlife Service, and provincial and state conservation agencies. Ducks are counted from fixed-wing aircraft on the same transects each year. Estimates of ducks and ponds seen from the air are corrected for visibility bias by conducting ground counts on a sample of transects. The estimates in Table 4.1 are not the entire continental breeding populations of ducks; a portion of each population (potentially $25 \%$ for mallards) nests outside the surveyed areas.

Although numbers of breeding ducks have fluctuated substantially from year to year, trend analysis suggests that total duck numbers are stable. This stable trend, however, is the result of increasing numbers of some species (e.g., gadwall, green-winged teal, shovelers and blue-winged teal) and decreasing numbers of others (e.g., pintails and scaup). Despite the improvements in duck numbers in the 1990's, there are still concerns about the long-term loss of both wetland and upland habitat in the prairie pothole region and the long-term outlook for duck populations in the future.

Duck populations have fluctuated substantially over time. The drought of the 1980's pushed many populations to near record low levels. The resiliency of these birds, however, was dramatically illustrated when most populations rebounded after water returned to the prairies in the 1990's. Pintails and scaup were exceptions to this rule; pintails because drought continued to plague their primary nesting areas in Alberta and
scaup for reasons apparently related to nutritional deficiencies on migration habitats. Duck populations will continue to fluctuate in the future as the numbers of wetlands on the landscape in north-central North America rise and fall with changes in the weather

## Giant Canada Goose Population

Giant Canada geese nested throughout Iowa prior to European settlement, but were extirpated from most of the Midwest, including Iowa, by 1900. The giant Canada goose restoration program initiated by the Iowa Conservation Commission in 1964, the forerunner to the Iowa Dept. of Natural Resources (IADNR), has successfully restored this species to most of its former nesting range in Iowa (see Giant Canada Goose Restoration). The giant Canada goose population in Iowa exhibited steady growth during 1965-2004, but has been stable in recent years (Fig. 4.2). Each summer, biologists and technicians estimate the numbers of adult Canada geese and goslings in their wildlife units. To obtain a statistically valid estimate of this population, an aerial survey is also conducted each spring. The results of the aerial survey conducted during April 2014 indicated the population was $84,694( \pm 16,829)( \pm 95 \%$ Conf. Limit), which is lower than the 2011 estimate of 105,738 $( \pm 11,780)$. Prior to 2005 , the population estimates made by wildlife biologists were nearly identical to the population estimates obtained from the aerial surveys. This indicates that the biologists' estimates accurately represented the growth rate and size of this population for most of the $20^{\text {th }}$ century.

## Waterfowl Harvests

Waterfowl harvests and hunter activity in Iowa are estimated annually by the USFWS (Table 4.2). Harvest estimates are calculated by combining the results of 2 surveys: 1) a survey of randomly selected hunters from the Harvest Information Program (HIP), which is used to calculate the total number of waterfowl killed, and 2) a survey that solicits duck wings and goose tails, which is used to estimate the species composition of the harvest.

Iowa's duck harvests have fluctuated substantially since 1961. The lowest harvests of all ducks and mallards occurred in the early 1960's, years of low duck populations and restrictive hunting regulations. The highest duck harvest was in 1979, a year with good duck numbers and, perhaps more importantly, excellent habitat conditions in Iowa due to above normal rainfall in August and September. Duck harvests began to decline in 1985, bottoming out in 1988 and 1989. Reasons for reduced harvests included smaller breeding populations and fall flights, shorter seasons, reduced bag limits, fewer hunters, and poor local habitat conditions. Duck harvests have increased in recent years as a result of improvements in duck numbers, liberal hunting regulations, and increases in numbers of active hunters.

Iowa's Canada goose harvest was relatively constant during 1967-85, but began to increase in 1986 as a result of increasing numbers of local giant Canada geese (Table 4.2). Canada goose harvests increased substantially after 1988, but were dampened in 1993 when restrictive Canada goose hunting regulations were implemented to reduce the harvest of Eastern Prairie Population (EPP) Canada geese. EPP geese nest on the west coast of Hudson Bay and are one of the two principle migrant Canada goose populations that fly through Iowa (the other consists of small Canada geese, commonly called "cacklers" or "hutchies,"
that nest on Baffin Island in the Arctic). The floods of 1993 may have also contributed to the decrease in the Canada goose harvest that year. Canada goose harvests resumed their increasing trend in the mid 1990's, and recently peaked at 78,600 in 2005 . The apparent drop in harvest in 1998 and 1999 may be an artifact of how the estimates were calculated rather than an actual change in harvest. At that time, the USFWS was converting from the old waterfowl stamp survey methodology to the new Harvest Information Program (HIP) survey. Harvest numbers from 1999 to the present are HIP estimates. Despite the Canada goose season being lengthened from 70 to 90 days in 2006 and to 98 days in 2010, Canada goose harvests have not increased in recent years. The smaller harvests in recent years likely reflect poor goose production in Iowa in those years.

The snow goose harvest in Iowa has declined since the early 1970's, despite record high numbers of snow geese in the Flyway in the 1990's and 2000's. Declining harvests resulted from shifting snow goose migration patterns, later migrations, increased use of refuges, and large numbers of older geese in the population. By the mid 1990's, the midcontinent light goose population was severely damaging Arctic breeding habitats. To increase harvests of light geese, more liberal hunting regulations were implemented (liberal bag limits, 107-day seasons) and a conservation order was implemented in 1999 to permit taking light geese after March 10 and to allow for hunting beyond the 107-day limit imposed by the Migratory Bird Treaty with Canada and Mexico. The harvest during the conservation order period in Iowa has ranged from 8,200 to 32,000 during 19992012. During the 1998-2011 regular light goose seasons, the harvest ranged from 0 to 15,000.

## Waterfowl Seasons

Iowa waterfowl hunters have experienced a wide range of duck and goose seasons since the USFWS began regulating waterfowl hunting in 1918 (Tables 4.3 and 4.4). Nearly every conceivable season-date combination has been tried in the past 90 years. Duck hunting regulations are inherently complex because they involve many species. The general lack of consistency in regulations, however, has made interpretation of the effects of these regulations on duck harvests very difficult. Goose hunting regulations, on the other hand, have been less complex and more consistent. The relative secure goose breeding habitat, along with consistently conservative seasons and bag limits, have enabled goose populations to prosper. The growing giant Canada goose population, however, has complicated traditional Canada goose harvest management. It is particularly challenging to develop hunting regulations that will increase harvests of local giant Canada geese while limiting harvests of migrant geese from Arctic and sub-Arctic regions.

## Waterfowl Banding

Ducks and geese are captured and banded with leg bands to obtain information on survival rates, hunting mortality, migration patterns and timing, and the relationships of harvest areas to production areas. Banding is conducted at the request of the USFWS and the Mississippi Flyway Council (MFC). Both state and federal personnel band ducks in Iowa, but IADNR personnel band all the Canada geese and more than $95 \%$ of the wood ducks (Table 4.5). Nearly 300,000 ducks and geese have been banded by IADNR personnel since 1964.

The USFWS, in concert with the MFC, determines banding priorities. In the 1960's emphasis was placed on banding bluewinged teal to evaluate special teal seasons. Winter mallard banding was conducted in the

1970's to supplement breeding grounds bandings and examine hen mortality during spring and summer. Wood duck bandings were used to evaluate Iowa's September duck seasons. Wood duck bandings are also important to measure the effects of hunting on wood duck populations, an aspect that has been particularly important since 2008 when the wood duck bag limit was increased from 2 to 3 birds per day. The IADNR has consistently cooperated with USFWS and MFC banding programs and has one of the top wood duck banding programs in the nation, accounting for $10 \%$ of all wood ducks banded in N. Am. in the last 10 years.

Canada goose banding has increased with the growth of the local Canada goose population in Iowa. Migrant Canada geese have also been banded as part of cooperative projects with the MFC. Canada goose banding will be increasingly important as the USFWS attempts to assess the impacts of special harvest regulations on resident Canada goose populations, which have been increasing, and migrant Canada goose populations, which have been stable or decreasing.

Table 4.3 continued: Duck and coot seasons in lowa.

DUCK SPECIES: Ma = Mallard, Wd = Wood duck, Bd = Black duck, $\mathrm{Cb}=$ Canvasback, Rh = Redhead, Ru = Ruddy duck, Bu = Bufflehead,
$\mathrm{Pt}=$ Pintail, $\mathrm{Wg}=$ Wigeon, $\mathrm{Sc}=\mathrm{Scaup}, \mathrm{Rn}=$ Ring-necked duck $\mathrm{Bt}=$ Blue-winged teal, $\mathrm{Gt}=$ Green-winged teal,
$\mathrm{Ga}=$ Gadwall, $\mathrm{Sh}=$ Shoveler, $\mathrm{Ct}=$ Cinnamon teal, $\mathrm{Md}=$ Mottled duck, $(\mathrm{Hn}=\mathrm{Hen}, \mathrm{Dr}=$ Drake $)$
$\mathrm{Cm}=$ Common merganser, Rm = Red-breasted merganser, $\mathrm{Hm}=$ Hooded merganser
SHOOTING HOURS: $S R$ to $S S=$ sunrise to sunset, $1 / 2$ SR to $S S=1 / 2$ hour before sunrise to sunset, $1 / 2$ SR to $1 / 2 S S=1 / 2$ hour before sunrise to $1 / 2$ hour before sunset, $1 / 2$ SR to $1 S S=1 / 2$ hour before sunrise to 1 hour before sunset. Shooting hours began at 12:00 noon on opening day for hunting seasons 1931-33, 1947-54, \& 1959-63. lowa set daily shooting hours at sunrise or later during 27 of the 72 hunting seasons between 1918-89. Federal regulations set daily shooting hours at sunrise or later during 16 of the 90 hunting seasons between 1918-2007.
LIMIT: BAG = Daily bag limit, POSS = Possession limit
POSS LIMIT = Twice the daily bag limit unless otherwise noted.
PS = Point System was used to determine the daily bag limit. The daily bag limit was obtained when the point value of the last duck taken, added to the point values of the previous ducks bagged, equaled or exceeded 100 points.
SPEC. REGULATIONS: Wood duck season was closed by Federal regulation from the 1918 through the 1940 season. Canvasback and redhead seasons were closed on the Mississippi River from 1975 thru 1979. Canvasback season was closed on the Mississippi River in 1980-82. Canvasback season closed on Pools 9 \& 19 on the Mississippi River from 1983-85. Canvasback season closed statewide 1936-37, 1960-63, 1972, 1986-93, 2002, 2008.
DUCK ZONE BOUNDARY (1) = a line running from the Nebraska-lowa border along l-80 to the lowa-Illinois border.
DUCK ZONE BOUNDARY (2) = a line running from the Nebraska-lowa border along State Hwy 175, east to State Hwy 37, southeast to U.S. Hwy 59, south to I-80 and along I-80 to the lowa-Illinois border.
DUCK ZONE BOUNDARY (3) = a line running from the Nebraska-lowa border along State Hwy 175, east to State Hwy 37, southeast to State Hwy 183, northeast to State Hwy 141, east to U.S. Hwy 30, and along U.S. Hwy 30 to the lowa-Illinois border.
DUCK ZONE BOUNDARY (4) = a line beginning on the South Dakota-lowa border at Interstate 29, southeast to Woodbury Co. Rd. D38, east to Woodbury Co. Rd. K45, southeast to State Highwy 175, east to State Highway 37, southeast to State Highway 183, northeast to State Hwy 141, east to U.S. Hwy 30, and along U.S. Hwy 30 to the lowa-Illinois border.
DUCK ZONE BOUNDARY (5) = The North Zone is all of lowa north of a line beginning on the on the South Dakota-lowa border at Interstate 29, southeast to State Highway 175, east to State Highway 37, southeast to State Highway 183, northeast to State Highway 141, east to U.S. Highway 30, and along U.S. 30 tp the lowa-Illinois border. The Missouri River Zone includes all lands and water in lowa west of Interstate 29 and north of Highway 175. The South Zone is the remainder of the state not in the North or Missouri River Zones.
(*SH) Steel shot required statewide for hunting all migratory gamebirds except woodcock.

## STEEL SHOT REGULATIONS HISTORY:

In 1977, no person could hunt waterfowl on all waters and a 150 yard zone thereto in Fremont and Mills Counties while possessing 12 gauge shotshells loaded with any shot other than steel. Drainage ditches, temporary sheet water and the Missouri River were exempt.
During 1978 \& 1979, no person could hunt waterfowl on all waters and a 150 yard zone thereto in Fremont and Mills Counties and on the Upper Mississippi Wildlife Refuge while possessing 12 gauge shotshells loaded with any shot other than steel. Drainage ditches, temporary sheet water, and the Missouri River in Mills and Fremont Counties were exempt. In 1980, Sweet Marsh in Bremer County, Big Marsh in Butler County, and the Princeton Area in Scott County, were added to the areas previously described in the steel shot regulations and the rule now applied to all shotgun gauges. In 1981, Green Island in Jackson County was added to the list of areas previously described where steel shot was required. During the 1982 through 1984 seasons, the previously described list of areas for steel shot remained the same. During the 1985 \& 1986 seasons, no person could hunt migratory game birds except woodcock on any lands or waters under the jurisdiction of the State Conservation Commission, the U.S. Government, or any county conservation board, or on all waters and a 150 yard zone adjacent to these waters, including reservoirs, lakes, ponds, marshes, bayous, swamps, rivers, streams, and seasonally flooded areas of all types, while possessing shotshells loaded with shot other than steel shot. Temporary sheet water, farm ponds less than 2 acres in size, and streams with water less than 25 feet in width where the hunting was occuring were exempt. In addition, no person could hunt waterfowl in the zone bounded on the west by the Missouri River, on the south by I-680, on the east by I-29 and on the north by the Soldier River, while possessing any shotshells loaded with shot other than steel shot.
From 1987 to the present, no person could hunt migratory game birds except woodcock on all lands and waters within the State of lowa while possessing any shotshell loaded with shot other than steel shot, or copper or nickle coated steel shot. In 1998, nontoxic shot was required for any shotgun shooting (except turkey hunting) on most DNR managed wildlife areas in lowa's prairie pothole region that had waterfowl production potential.
(*HIP) First year migratory bird hunters in lowa registered (by phone) for the federal Harvest Information Program (HIP).

Page 3

Table 4.4 continued: Goose seasons in lowa.

Table 4.4 continued: Goose seasons in lowa.

Table 4.4 continued: Goose seasons in lowa.

GOOSE SPECIES: Ca = Canada goose, $\mathrm{Sn}=$ Snow goose, $\mathrm{Wf}=$ White-fronted goose, $\mathrm{Br}=$ Brant, Ro = Ross's goose
SEASON LENGTH: Maximum number of days the season could be open.
SHOOTING HOURS: SR to $S S=$ sunrise to sunset, $1 / 2$ SR to $S S=1 / 2$ hour before surrise to sunset, $1 / 2$ SR to $1 / 2$ SS= $1 / 2$ hour before sunrise to $1 / 2$ hour before sunset, $1 / 2 S R$ to $1 S S=1 / 2$ hour before sunrise to 1 hour before sunset. $1 / 2$ SR to $S S / 1=1 / 2$ hour before sunrise to sunset in all of state except SW Zone where shooting hours were 1/2 hour before sunrise to 1:00 PM until Dec. 1 in 1991 and until Nov. 29 in 1992, then $1 / 2$ hour before sunrise to sunset thereafter. $1 / 2$ SR to SS $1 / 2=1 / 2$ hour before sunrise to $1 / 2$ hour after sunset.
LIMIT: BAG = Daily bag limit, POSS = Possesion limit
SW ZONE(1) = that portion of the state south and west of a line running from the lowa-Missouri state line along US Hwy 71 to state Hwy 92 and west on Hwy 92 to the Nebraska-lowa border.
SW ZONE(2) = that portion of the state south and west of a line running from the lowa-Missouri state line along U.S. Hwy 71 to I-80, west on I-80 to U.S. Hwy 59, north on U.S. Hwy 59 to State Hwy 37, then NW on Hwy 37 to State Hwy 175, and west on Hwy 175 to the Nebraska-lowa border.
GOOSE ZONE BOUNDARY (1) = a line running from the Nebraska-lowa border along state Hwy 175, southeast to State Hwy 37, east to U.S. Hwy 59, south to I-80, and along I-80 to the lowa-Illinois border. This was the same boundary used to divide the north and south duck zones during 1993-2003.
GOOSE ZONE BOUNDARY (2) = a line running from the Nebraska-lowa border along state Hwy 20. This change was made in the 2004 season and was maintained through the 2008 season.
GOOSE ZONE BOUNDARY (3) = a line running from the Nebraska-lowa border along State Hwy 175, east to State Hwy 37, southeast to State Hwy 183, northeast to State Hwy 141, east to U.S. Hwy 30, and along U.S. Hwy 30 to the lowa-Illinois border. The duck and goose zone bounaries were identical from from 1993-2003. The goose zone boundary was moved to Hwy 20 from 2004-2008. In 2009, the goose zone boundary was changed to match the duck zone boundary, i.e., along Hwy 30.
GOOSE ZONE BOUNDARY (4) = a line beginning on the South Dakota-lowa border at Interstate 29, southeast to Woodbury Co. Rd. D38, east to Woodbury Co. Rd. K45, southeast to State Highwy 175, east to State Highway 37, southeast to State Highway 183, northeast to State Hwy 141, east to U.S. Hwy 30, and along U.S. Hwy 30 to the lowa-Illinois border.
GOOSE ZONE BOUNDARY (5) = The North Zone is all of lowa north of a line beginning on the on the South Dakota-lowa border at Interstate 29, southeast to State Highway 175, east to State Highway 37, southeast to State Highway 183, northeast to State Highway 141, east to U.S. Highway 30, and along U.S. 30 tp the lowa-Illinois border. The Missouri River Zone includes all lands and water in lowa west of Interstate 29 and north of Highway 175. The South Zone is the remainder of the state not in the North or Missouri River Zones.
(*SH) Steel shot required statewide for hunting all migratory gamebirds except woodcock. See lowa's Duck and Coot Seasons for a complete history of steel shot regulations in lowa.
(*HIP) First year migratory bird hunters in lowa registered (by phone) for the federal Harvest Information Program (HIP).
SPECIAL REGULATIONS: Ross's goose season was closed by Federal regulation from 1942-61.
${ }^{\text {a }}$ The daily limit was 2 Canada geese through Oct. 31 and 1 thereafter except in the south zone where it was 2 after Nov. 30 .
${ }^{\mathbf{b}}$ The special 2-day September Canada goose season was only open in the north zone west of Hwy 63.
${ }^{\text {c }}$ A conservation order was issued by the USFWS to permit the taking of light geese (snow + ross) after the regular season,
including after March 10, the last day regular waterfowl seasons can be open.
Hunters could use electronic calls and unplugged shotguns and hunt until $1 / 2$ hour after sunset.
Hunters had to be fully licensed to hunt waterfowl in lowa (no Fed. Mig. Bird stamp) and registered with HIP.
${ }^{d}$ This special September Canada goose season was only open in the Des Moines and Cedar Rapids/lowa City zones.
e This special September Canada goose season was only open in the Des Moines, Cedar Rapids/lowa City and Cedar Falls/Waterloo zones.

## UPLAND WILDLIFE

The Iowa Department of Natural Resources (IDNR) conducts 2 statewide surveys to monitor upland game populations in Iowa, the August Roadside survey and the Small Game Harvest survey.

August Roadside Survey is conducted each year by IDNR Enforcement and Wildlife Bureau personnel throughout the state of Iowa during the first half of August. The survey generates data from 21530 -mile routes on ring-necked pheasants, bobwhite quail, gray partridge, cottontail rabbits, and white-tailed jackrabbits. Counts are conducted on sunny, cool mornings with heavy dew. All comparisons are based on total routes run.

The small game harvest survey is a mail survey of Iowa small game hunters conducted following the small game hunting seasons. Each year a random sample of small game hunters (5\% of licensed hunters) are send a postcard and survey participants are asked where they hunted, which species they hunted, how many days they hunted, and how many of each species they harvested.

The data from these 2 surveys form the basis for historical information on upland game populations in Iowa and are summarized in the historical text and tables. Both surveys have been conducted annually since 1962. The annual August roadside
survey report can be found on the DNR's website at http://www.iowadnr.gov. The results of the annual small game harvest survey can be found at the end of this report.

## HISTORICAL SUMMARY OF POPULATIONS AND HARVEST

## Ring-necked Pheasant

The genus Phasianus or true pheasant is native to Southeast Asia. The ring-necked pheasant now found in Iowa has been classified as (Phasianus colchicus torquatus). This name suggests a cross between 2 of the true Asiatic pheasants. One the Rion Caucasian (Black-necked) pheasant (Phasianus colchicus colchicus) native to the area between the Black and Caspian Seas and the true Chinese ring-necked pheasant (Phasianus torquatus torquatus) found in eastern China and northwestern Indo-China.

The ring-necked pheasant was first successfully introduced into the United States in the Willamette Valley of Oregon by Owen Denny in 1882. Mr. Denny transported wild birds from China to the US to establish a population on his land. It is believed that the majority of the pheasant range in the US was stocked with birds from this original wild foundation or other wild birds from China.

Early records for Iowa are limited, but accounts suggest attempts were made to establish pheasants in Iowa as early as 1884, but the first recorded successful release was an accidental release following a wind storm of approximately 2,000 birds from the William Benton game farm in Cedar Falls. The source of Mr. Benton's birds is not known with certainty, but reports say they were from an importer in Tacoma,

Washington and thus very likely wild birds from China or wild birds from the Owen Denny Farm. The conservation department mentions pheasants for the first time in 1910. Early on eggs were purchased from breeders (wild or tame is unknown) and given to landowners to raise and release statewide, the 1910 biennial report indicates 6,000 eggs were distributed to applicants in 82 counties. Egg distribution met with poor success and the conservation department established a hatchery in 1913 and by 1914 mostly young birds were distributed ( 1,088 that year). Another 10,912 birds were distributed statewide from 1915-16. Records show all northwest counties received 200-800 bird plantings of pheasants from 1915 to 1918, with a planting of 2,500 in Winnebago County.

In 1905, it was generally assumed that southern Iowa had better pheasant habitat than northern Iowa. The existence of this belief is supported by the fact that up until 1913 it was customary to make stockings in timber. It is interesting to note Iowa's pheasant populations reached their highest abundance in NW and NC Iowa. The early success, 1920-40's, of pheasants in north central Iowa was undoubtedly due to the abundance of grassy habitats (tame and native hay, oats, flax, and prairie pothole wetlands) interspersed with weedy crop fields.

Pheasants did extremely well in northern Iowa with crop depredation reported in 1923, with the first open season in 1925. Policy changed in 1924-25 and wild birds and eggs were trapped and moved in an effort to establish populations in southern Iowa. Between 1925-1931 some 26,498 wild birds and 60,000 wild eggs were gathered from areas of undue abundance in northern Iowa and distributed to other regions, mostly southern Iowa. From 1927-30 and additional 10,211 birds and 31,372 eggs were distributed in southern Iowa counties. During, 1929-30 the average southern Iowa county received
over 500 birds. However, by 1936 the policy on stocking had changed:
" The old policy of stocking birds without paying attention to the environment has been discontinued ... for instance, during the past 20-25 years there have been thousands of pheasants released in southern Iowa and ... in except a few cases pheasants disappeared after two or three generations in most counties."

The state game farms were shut down in 1932, but following several bad weather years it was re-established in 1938. Populations recovered with good weather in the 1940's and stocking was greatly reduced, approximately 4,000 chicks and spent adults in 1943. The state game farm operated at approximately the same level until 1961. Through the 1940-50's it became increasingly evident that pen raised birds were not contributing to wild pheasant numbers. Similar to what had been done in 1924-25, in 1955 a new policy of trap and transfer of wild birds was started in southern Iowa. Increasing populations in Union and Adair counties were trapped (1,375 birds) and transplanted to Ringgold, Decatur, Wayne, Washington, and Appanoose counties. Also new wild birds were brought to the state game farm. These new "wild" birds were distributed to unoccupied range (Washington, Keokuk, Henry, Davis, VanBuren counties) thru 1973. The state game farm was closed in late 1970's and dismantled.

Iowa's first pheasant season was held October 20-22, 1925 in Kossuth, Humboldt, Winnebago, Hancock, Wright, Cerro Gordo, Franklin, Mitchell, Floyd, Butler, Grundy, Blackhawk and Bremer counties. The hunting season opened $1 / 2$ hour before sunrise and ended at noon with a bag limit of 3 cocks. It appears the decision to open counties to hunting in these early years was based largely on pheasant crop depredation complaints as annual pheasant censuses, predecessor to the August Roadside Survey, were not begun
until 1935. Flush count records show 7 men flushed 850 pheasants in 5 hours in Hancock county in 1931. By 1945 most of northern Iowa was open to hunting and by 1965 all of Iowa, except a few southeastern counties, was open to pheasant hunting. The entire state was opened to hunting in 1976. Historically (1930-50's), the NW, NC, and C regions had Iowa's highest pheasant densities (Fig. 5.1). However, intensified agriculture has led to a decline in pheasant populations since the 1960's (Fig. 5.2). Regionally, the greatest declines have occurred in the NC, C, and SW regions (Fig. 5.7). By the early 1970's southern Iowa had become the states premiere pheasant range.

Populations have declined following severe winter weather in 1964-65, 1966-67, 1978-79, 1981-82, 2000-01, and 2007-11, with recoveries occurring in years with milder winters (Table 5.1). While the number of broods sighted/30-mile route has also fluctuated with the severity of the winter (Fig. 5.3), the all-time lows recorded in 1983, 1984, 1993, 1999, 2001, and 2007-10 were the results of very cool and/or wet conditions during spring and early summer (Table 5.2; Fig. 5.3). Observed brood sizes have declined slightly since 1962, with the 2010 estimate of 4.0 chicks/brood the lowest ever recorded (Table 5.2; Fig. 5.3). Modest recoveries of all survey parameters occurred between 1984 and 1996 with the enrollment and seeding down of 2.2 million acres of row crops in the 10 -year federal Conservation Reserve program (CRP). Pheasant populations in historical ranges, northern and central regions, have rebound since the inception of CRP (Fig 5.7). Populations in the southern regions initially responded to CRP the same way northern and central populations did, but have declined since 1992. Declines in SW and SC regions, in particular, are likely related to wet weather during the nesting season, lack of habitat management on CRP acres and other land use changes. The pheasant season opens the last

Saturday in October and runs through January $10^{\text {th }}$, statewide with a bag/possession limit of 3/12 roosters (Table 5.10). Shooting hours are 8 a.m. to $4: 30$ p.m. Iowa's first youth pheasant season was held during the 1997-98 hunting season. Youth hunting was allowed statewide for resident hunter's 15 years or younger whom a licensed adult accompanied. The youth pheasant season opens the weekend proceeding the regular season. Bag limit is 1 rooster/day with 2 in possession after the first day (Table 5.10).

## Bobwhite Quail

Our native bobwhite was probably never very abundant on Iowa's virgin prairie; most populations were likely restricted to the prairie-timber edges of Iowa. Early settlement changed Iowa's landscape forever. At least initially these changes proved to be a boom to Iowa's quail population. Between 1860-90 settlers began carving up Iowa a $1 / 4$ section at a time, but early settlers lacked timber and wire to make fences, so they planted Osage hedges instead. Three to 6 miles of some of the finest quail cover ever grown in ever $1 / 4$ section, all within spitting distance of newly planted "weedy" grain fields. Quail populations exploded like never seen before or likely to be seen again. Quail could be found in every county, but these conditions could not last. By 1920 reports
show quail populations beginning to decline as farming practices improved and hedgerows were replaced with barbed wire fence. The 1931-32 winter quail survey reported population densities of 1 quail per 20-40+ acres in the northern third of the state, 1 quail/6-20 ac. in the central third and 1 quail/1-6 ac. in the southern third of the state. However, quail populations have declined steadily, both nationally and in Iowa since the 1930's. Large scale landscape changes and clean farming practices are considered the major factors in this decline. Since survey procedures were standardized in the early 1960's the mean number of quail/30 miles sighted on the August roadside survey has fluctuated over the years with significant declines occurring since 1977 (Fig. 5.6). This decline, along with the severe fluctuations in SW and SC Iowa in recent years, are related to losses in shrubby habitat and clean farming practices that have occurred since row-crop agriculture expanded in the mid 70's and early 80's (Fig. 5.8). Similar to pheasants, quail numbers have declined sharply following harsh winters in 1964-65, 1966-67, 1978-79, 1981-82, 2000-01, and 2007-10. (Fig. 5.8).

Quail have been hunted in Iowa since settlement. The first bag limit was set in 1878 at 25 birds/day, it was reduced to $15 /$ day in 1915. The season was closed in 1917 and a limited season reopened in 1933. Currently the season opens the last Saturday in October and runs through January $31^{\text {st }}$, statewide, with a bag/possession limit of $8 / 16$ birds. Shooting hours are 8 a.m. to $4: 30 \mathrm{p} . \mathrm{m}$. (Table 5.11).

## Gray Partridge

Senator H.W. Grant of Waterloo made the first release of Hungarian or gray partridge in Iowa in Blackhawk county in 1902, but all 50 birds died. The first successful release of Huns in Iowa occurred in Palo Alto county in 1905. This release constitutes Iowa's first wild stock. Successful releases were made in Humboldt county in 1906, O'Brien in 1909, and in Kossuth in 1910. By 1914 most northern Iowa counties had received standardized releases of 20 pairs each. All releases, similar to pheasants, were made on leased timbered lands. Reports show many local farmers were surprised when the bird promptly moved to the nearest prairie upland. By 1932 it is estimated the state conservation commission had stocked 20,000+ partridge in Iowa. Most plantings were in northern Iowa, although a few were attempted in south central Iowa; all southern attempts failed. The birds gained their strongest hold in northwest Iowa in Osceola, O'Brien, Dickinson, and Clay counties and were generally present in most northern Iowa counties by 1940.

While numbers of other upland game birds have decreased over time, the number of gray partridge sighted on roadside counts had been increasing until 1990 (Fig. 5.6). Not only had the mean number partridge per 30mile route increased statewide, but partridge
populations had expanded their range from the NW and NC regions to all other regions of the state by 1986 (Fig. 5.9). While losses of woody cover and nesting cover have created less favorable conditions for pheasant and quail, partridge have been more adept at coping with row-crop expansion. The statewide increase in partridge numbers between 1983-89 can be attributed a drought during these years and improved nesting conditions on land enrolled in CRP. Following the drought populations have returned to levels seen prior to 1983 (Fig. 5.6). Huns were imported to this country from the arid, steppe region of southeastern Europe and northern Asia, and research has shown they do not reproduce well in this country during years with wet springs.

Iowa's first partridge season was held in 11 northwestern counties in 1937-39. Partridge season was standardized in 1989 to opens the second Saturday in October and runs through January $31^{\text {st }}$, statewide, with a bag/possession limit of $8 / 16$ birds. Shooting hours are 8 a.m. to 4:30 p.m. (Table 5.12).

Eastern Cottontail
Little is known about the presettlement distribution of cottontail rabbits in Iowa. Cultivation by man no doubt favored rabbits much the same way it favored quail at the turn of the century. Cottontails prefer habitats similar to quail, favoring shrubby-grassy edge
habitats. Cottontails may have up to 6 litters a year in Iowa and reproduce best during warm moderately wet springs. Numbers of cottontail rabbits observed on the August roadside survey have fluctuated with changing land use and weather conditions (Fig. 5.6). Hunter interest has declined in recent years (Fig 5.12). Cottontails have been hunted in Iowa since settlers first arrived. The cottontail season was standardized in 1978 and opens the first Saturday in September and runs through February $28^{\text {th }}$, statewide, with a bag/possession limit of $10 / 20$ rabbits. Shooting hours are sunrise to sunset (Table 5.13). The rule regarding the opening day of the cottontail season was changed in 1997 to open the 1997-98 season on Sept. 1st. This change in date allows inclusion of the Labor Day weekend in all years. It was changed again in 2008 to open the Saturday before Labor Day to allow youth hunters to participate in the opener.

## White-tailed Jackrabbit

Before settlement white-tailed jackrabbits could be found everywhere in Iowa, except for a few southeastern counties. They appear in greatest abundance on the glaciated soils of the Des Moines Lobe and the Missouri Loess soils of northwestern Iowa. They are most at home on the wideopen expanses of prairie/wetland/pasture habitat types, although moderate cultivation favors the species. Dry growing seasons appear conducive to jackrabbit abundance as population's decline in wet years. Jackrabbit counts have declined greatly over time, closely paralleling the losses of pasture, hay,
and small grain acreage's. Because of this downward trend the bag/possession limit was reduced from $2 / 4$ to $1 / 2$ following the 2005-06 hunting season The hunting season on jackrabbits was closed during 2011-12 hunting season because of continued declines on DNR roadside surveys. It may be reopened if populations recover due to landscape changes like grass based biomass.

Jacks have been hunted in Iowa since the time of settlement. Conservation officers reported hunters killing 180+ jacks on two circle hunts in Carroll and Buena Vista counties during the winter of 1960 . Historic trends in jackrabbit population, harvest, and hunting seasons can be found in tables (5.3, 5.6, and 5.13).

A random survey of licensed hunters was conducted following the 2012 small game season to determine the size and distribution of Iowa's small game harvest. Survey questionnaires were mailed to 8,315 license holders. Survey participants were asked which species they hunted, how many days they hunted, and how many of each species they harvested. Survey participants returned 3,275 usable questionnaires for a response rate of $39 \%$. The DNR sold 207,884 unique hunting licenses in 2012-13. Based on survey
responses an estimated 62,192 license holder's hunted small game (pheasant, quail, partridge, cottontail, or squirrel). This is a 5\% increase in small game hunters compared to the year before.

By residency, the number of resident small game hunters increased $6 \%$, from 52,507 in 2011 to 55,710 in 2012, while the number nonresident small game hunters fell $8 \%$ from 7,079 in 2011 to 6,482 in 2012. Pheasant were the most commonly reported species hunted by small game hunters (76\%), while squirrels where the second most sought after species with $35 \%$ of small game hunters indicating they hunted squirrels.

Hunters from 44 different states visited Iowa last fall to hunt. Over $52 \%$ of Iowa's nonresident hunters came from 4 states, Minnesota, Wisconsin, Michigan, and Illinois in that order. The typical small game hunter reported hunting a little over 8 days last fall.

Ring-necked Pheasant - An estimated 47,180 pheasant hunters ( $23 \%$ of licensed hunters, $76 \%$ of small game hunters) took to Iowa's fields last fall and harvested 158,099 roosters (Table 5.6 and 5.9). The number of pheasant hunters increased $3 \%$, while total harvest increased $45 \%$ compared to 2011 estimates. Roadside counts showed populations increased $18 \%$ compared to 2011, so the increase in hunters and harvest was expected. An estimated 5,742 nonresident hunters contributed to Iowa's total estimate of pheasant hunters. Iowa's peak year for nonresident pheasant hunters was 1997 with 50,349 . Resident hunter numbers increased $5 \%$ while the number of nonresident pheasant hunters declined $-11 \%$ (Table 5.7). This is the first increase in pheasant hunters since 2005 (Table 5.9).

Resident hunters hunted an average of 6.3 days last fall and harvested 3 birds during the season. Nonresident pheasant hunters
averaged 4.3 days afield and harvested 4 birds for the season. Hunter success (harvest/day) was highest through the first 2 weekends of the season. Approximately $38 \%$ of the total pheasant harvest occurred in the first 9 days of the 2012 season. Fifty-six percent of pheasant hunters reported hunting 4 days or less. Resident hunters accounted for $87 \%$ of the total pheasant harvest.

The improved winter and spring weather conditions in 2012, as predicted, led to the first increase in pheasant harvest since 2005.
 The pheasant harvest estimate however, remains $-70 \%$ below the 10 -year average, and $-86 \%$ below the historic average harvest of 1.1 million roosters (Table 5.6). Unfortunately Iowa's weather pattern for 2013 returned to a snowy winter and a wet and cold spring, thus it does not appear the population will continue the rebound in 2013.

Bobwhite Quail - Approximately 8,769 quail hunters ( $4 \%$ of licensed hunters, $14 \%$ of small game hunters) harvested 20,474 quail during the 2012 quail season (Table $5.6 \& 5.9$ ). Hunter numbers declined $-7 \%$ while harvest improved significantly compared to 2011 estimates. Quail hunters averaged 5 days a field and harvested 2 birds for the season (Table 3). Fifty-five percent of the quail harvest occurred in the first month of the 2012 season (Table 4). Sixty-two percent of quail hunters hunted 4 days or less. Resident quail hunters accounted for $95 \%$ of the total quail harvest. Roadside counts showed quail numbers had increased $63 \%$ over 2011 estimates (Table 5.3), thus the improved hunter harvest was expected(Table 5.7).
Gray Partridge, Eastern Cottontail and White-tailed Jackrabbit - Hunter trends, season dates, and harvest for these species can be found in Tables (5.6, 5.9, 5.12, and 5.13) and Figures (5.6, 5.9, 5.10, and 5.12).

Table 5.1. Mean number of pheasants counted/30-mile route on the August roadside survey regionally and statewide (1962-present). Severe winter weather preceded the August counts in 1965, 75, 79, 01, $0408,10,11$. Abnormally wet weather occurred during 1973, $82,84,95,99,01,08,1 ミ$ nest seasons. Winter sex ratio and cock harvest data are statewide estimates. Sex ratio counts were done the year succeeding the year listed.

## PEREGRINE FALCON RESTORATION

The peregrine falcon (Falco peregrinus) was extirpated as a breeding bird from the eastern U.S. by 1964. In the Midwest, peregrines formerly nested on cliffs along Lake Superior, Lake Michigan and the upper Mississippi River, plus suitable palisade areas. The upper Mississippi River area was the major historic nesting area for peregrines in the Midwest, with an estimated historic population of $30-35$ pairs (Tordoff 1986). Most of Iowa's historic peregrine nesting occurred on the Mississippi River bluffs of northeastern Iowa in Allamakee, Clayton, Dubuque, and Clinton counties (Anderson 1907, Allert 1939, Pierce 1940), but nesting also occurred on the palisades of the Cedar River in Linn and Johnson counties (Bailey 1918) and along the Cedar River in Black Hawk County (Anderson 1907). A nest was also reported at the mouth of Beaver Creek in Polk County (DuMont 1931). Prior to reintroduction, the last documented nests were noted in 1955 and 1956 at two of six eyries in Allamakee County (Berger and Mueller 1969), although there were reports of a nest with two eggs in Allamakee County in 1964 and a nest with downy young at Blackhawk Point, Allamakee County in 1967 (Roosa and Stravers 1989). Pesticides, specifically DDT, were the primary cause for the dramatic decline in the peregrine population. Until 1998, the peregrine falcon was a federally and state listed endangered species. The bird was federally delisted in 1998, but remains on the state endangered species list.

In an effort to guide recovery of the peregrine falcon to the eastern U.S., an Eastern Peregrine Recovery Plan (EPRP) was developed. The overall goal of this
plan was to establish a viable peregrine falcon population consisting of 175 breeding pairs, which is half of the prepesticide population. For each region of the eastern U.S., EPRP set a goal of 20-25 breeding pairs. Iowa falls under the Midwestern and Great Lakes regional plan (MGLRP). As part of the MGLRP, Iowa set a goal of establishing 5 breeding pair by the year 2000 with an ultimate goal of 10 breeding pair for a viable population. To achieve this goal, the Wildlife Diversity program planned to release 55 peregrines in the first 5 years. The "magic number" of birds released to get one breeding pair return is about 13. A maturing bird is expected to return to a release site within 2-3 years after release and establish a territory within that area. As a result, no release site will be used for more than 2 years to avoid confrontations with adult falcons and hack birds.

## Iowa's Peregrine Falcon

 Restoration project began in 1989 with the release of $10(2 \mathrm{~F}, 8 \mathrm{M})$ birds in Cedar Rapids from the Telecom USA building. There was one mortality during this first release when a bird collided with a building. Releases continued for the second year at the Cedar Rapids release site with 13 falcons (3F,10M) in 1990. Two of these birds, 1 male and 1 female, died as a result of collisions with buildings. During the 1990 hacking process a subadult male (T6?- apparently from 1989 C.R. release) showed up in Cedar Rapids and regularly interacted with hacked birds.In 1991, a second release site was selected for the third year of the project. A total of 19 birds ( $8 \mathrm{~F}, 11 \mathrm{M}$ ) were released in 1991 at the First Baptist Foundation of the Elsie Mason Manor in

Des Moines. Similar to the 1991 Cedar Rapids release, a subadult male (T93-from 1990 Cedar Rapids release) appeared for a brief period of time. Little to no aggressive interactions were observed between this subadult and the hacked falcons. During 1991, peregrines were observed in Cedar Rapids, Davenport and Keokuk; however, no nests were located. A second release was not attempted at the Des Moines site during 1992 because two falcons attempted to nest on the American Republic Insurance building. The female (R13 - Kansas City 1990) laid 5 eggs total. One egg rolled off the alcove ledge and another was cracked. The 3 remaining eggs were laid in a different alcove and never incubated. The male at this site was X20 from the 1990 Cedar Rapids release. This was the first nesting attempt in Iowa in nearly 30 years.

Elsewhere in the state during 1992, falcon pairs established two additional territories. A male falcon in Cedar Rapids successfully attracted a mate in mid-May, but it was too late in the season for breeding. The pair engaged in courtship flights and investigated the nest box on the Firststar Bank building, but did not actually attempt to nest. In the Quad Cities, a pair appeared to be incubating eggs under the Centennial Bridge; however, there were no observations of feeding in late-June. The site was investigated in September, but no eggs, egg fragments, dead young or even a definitive nest site was found.

The third release site chosen for releases in 1992 (the $4^{\text {th }}$ year of the project) was Davenport. However, the arrival of a falcon pair precluded this site from release since the territorial adults could potentially harm the young hacked birds. As a result, 8 birds ( $2 \mathrm{~F}, 6 \mathrm{M}$ ) were released from the Laurel Building in

Muscatine during 1992. A male Cedar Rapids bird (T95 - 1990) appeared after the hacked birds fledged. T95 engaged in mock combat with the young and occasionally harassed them at the hack site, but he did not harm any of the young. Of the 8 birds released at Muscatine, 2 died, both males.

In 1993, there was much falcon activity across the state. We had 2 successful peregrine falcon nests in Iowa. The falcon pair returning to the American Republic Insurance building was the same male (X20) and female (R13) who attempted to nest in 1992. Shortly after their return, the male (X20) was found decapitated after a three-bird territorial dispute. The "winning" male did not remain in the area. The female (R13) eventually mated successfully with a third male, T93 (from 1990 Cedar Rapids release), that came to Des Moines. This pair successfully hatched and raised 3 young. In early July, one of these young was found dead in the air conditioning unit of the American Republic Insurance Building.

The second successful nest occurred in Cedar Rapids. The male was identified as X64 (Des Moines - 1991) and the female as R49 (Des Moines 1991). This pair laid 4 eggs and hatched 2. Of the two young, one died of exposure from stormy weather. The Iowa Falconer's Association donated a young male to foster into the nest. The adults accepted the "implant" along with the remaining female chick. Both young fledged successfully from the nest.

A third nesting occurred in Iowa during 1993 at the Centennial Bridge in Davenport. A pair was observed demonstrating nesting behavior, but that soon changed about the time young should hatch. Closer observation of the nest site
did not reveal young or eggs, however, a possible scrape was located along with falcon prey remains. A decomposed body of a female falcon (W24 - Kenosha, WI) was found trapped in the I-beam of the bridge. It is possible that this bird was the nesting female. Once she became trapped, the male abandoned the nest and attracted a new female (R95 - Colonnade, MN). By this time, it was too late in the season for nesting.

At Muscatine, a single male (C/M - Muscatine, 1992) returned to the site, but did not attract a mate. Because of the return of this bird, a second release was not made at this site.

During 1994, two falcon pairs nested successfully, marking the second year in a row for nest success. The birds at Firststar Bank in Cedar Rapids were the same, R49 and X64. They laid and hatched 4 eggs ( $2 \mathrm{~F}, 2 \mathrm{M}$ ), but one female died soon after hatching. Another chick was treated for trichonomoniasis (Frounce) and released. All three young fledged successfully. The second successful nest was at the same site in Des Moines - the American Republic Insurance building. This pair was also the same birds from 1993, R13 and T93. Their first nesting attempt on the east side of the building was unsuccessful as one egg rolled off the ledge and the other two eggs were abandoned. The birds moved to the west side where they laid and hatched three young ( $1 \mathrm{~F}, 2 \mathrm{M}$ ), all of which fledged successfully. The young female later died as a result of a collision with a building and one young male died of unknown causes. There was no known nesting attempts at either Davenport or Muscatine, however, a bird was observed during the winter at the Centennial Bridge in Davenport.

The original goal established by

EPRP of 20-25 nesting pair was met and replaced with a new regional goal of 40 territorial pairs. This new goal was met and surpassed in 1993. By 1994, the midwestern region had 61 territorial pairs with 41 successfully nesting. As a result of meeting the regional goal, many states tapered off falcon releases. However, Iowa's goal of establishing 5 nesting pairs by the year 2000 did not look promising without further releases. Furthermore, many did not consider the Midwestern population recovered since there was very little nesting on natural eyries aside from cliffs in northern Minnesota and Michigan.

In order to address the need for more releases in Iowa, a Peregrine Falcon Recovery Team (PFRT) was formed to continue releases with the hope of establishing a sustainable peregrine population that requires little or no maintenance or manipulation. The (PFRT) hoped to continue urban releases in strategic locations along the Mississippi and inland along known flyways. The group would also evaluate the possibility of releasing birds along the cliffs of NE Iowa.

The 2 falcon pairs in Cedar Rapids and Des Moines nested successfully once again in 1995, marking the third consecutive successful nesting season in Iowa. The Cedar Rapids pair produced four eggs and hatched three young ( $1 \mathrm{~F}, 2 \mathrm{M}$ ). All three young fledged successfully. One male was later found dead as a result of a collision. The Des Moines pair laid four eggs and hatched three females, all of which fledged successfully.

Iowa has been able to maintain its two nesting falcon pairs in Des Moines and Cedar Rapids. Regionally during 1996, there were 87 territorial pairs of
which 45 nested successfully. The Cedar Rapids pair (still the same male and female) again produced 3 birds ( $1 \mathrm{~F}, 2 \mathrm{M}$ ), one egg did not hatch. All 3 birds fledged successfully. The Des Moines pair hatched 3 young, but one mysteriously disappeared leaving only 2 males to fledge successfully. This year marked the start of additional falcon releases with the hopes of achieving the goal of 5 breeding pair by the year 2000. The Peregrine Falcon Recovery Team, who generated the funding and volunteers to conduct the releases, spearheaded these releases. Mason City released 7 birds total (3F,4M), two of which (both females) came from Iowa City during the hacking process. Iowa City was in the process of hacking 3 birds ( $2 \mathrm{~F}, 1 \mathrm{M}$ ), when a wild peregrine showed up at the release site and killed the male. The two remaining females were transported to Mason City to fledge for safety of the birds. There were no releases at Burlington due to mortality prior to placing the birds in the hack box.

The falcon project met with mixed success in 1997. Both falcon pairs returned to nest in Cedar Rapids and Des Moines, however, the Des Moines pair exhibited problems. The female laid her eggs in an alcove on the American Republic Insurance Building that did not have pea gravel in the bottom, so the eggs got wet. We put gravel in, but it was too late. The female abandoned the eggs. She did, however, lay 2 eggs in another alcove and 1 in yet another. To facilitate incubation, we moved the lone egg in with the 2 , but later one was kicked out of the scrape, one was cracked and the other was abandoned. Two of the 6 eggs were sent for analysis to try and provide answers for the aberrant behavior of the Des Moines female. On the bright side, the Cedar Rapids pair laid 4 eggs and successfully
fledged 2 (both males). Elsewhere in the state, the PFRT continued releases at the Mason City site with 3 young ( $1 \mathrm{~F}, 2 \mathrm{M}$ ), one of which died from injuries received after colliding with a fence. Iowa City did not release birds in 1997, but Bob Anderson started his efforts of releasing birds on the natural eyries of NE Iowa. He released 4 birds in 2 batches of two $(2 \mathrm{~F}, 2 \mathrm{M})$ at a hack site situated on the cliffs overlooking the Iowa River near Bluffton. Two of the birds were equipped with radio transmitters, but were not tracked successfully for very long due to the topography interfering with the transmission of the signals.

Things were back on track for 1998. Both falcon pairs nested successfully in Cedar Rapids and Des Moines. The Des Moines pair produced 3 young ( $1 \mathrm{~F}, 2 \mathrm{M}$ ) as did the Cedar Rapids pair ( $2 \mathrm{~F}, 1 \mathrm{M}$ ). There was no evidence of additional eggs in Des Moines, however, there were 5 eggs in Cedar Rapids. As for other releases in the state, Mason City concluded its final peregrine release in 1998, sending off 15 falcons (4F,11M) without a hitch and Louisa had its first release with 4 young ( $3 \mathrm{~F}, 1 \mathrm{M}$ ). Bob Anderson continued his cliff-site releases in 1998. However, he changed the release site from Bluffton to Effigy Mounds National Monument. The latter location is an exceptional bluff overlooking the Mississippi River. Two psuedo-rocked hack boxes were mounted on the bluff face. A total of nine birds ( $5 \mathrm{~F}, 4 \mathrm{M}$ ) were released from the sight. Radio transmitters on the birds indicated no mortality up to dispersal. Unfortunately, two of the Effigy Mounds birds died during the spring of 1999 due to a possible collision and a drowning.

The Peregrine Falcon Recovery Project had a slight change in direction
during 1997. The decision was made to no longer allow urban releases, except for two grandfathered sites that already had the steps in motion for 1998 releases. Those grandfathered sites were Mason City and Louisa. The Mason City site releases were completed with the hacking of 15 falcons in 1998, and Louisa continued releases through 2000. The reasoning behind this decision was that the transition of falcons nesting in urban areas to natural cliff sites was not occurring as originally thought. In fact, some studies indicate that urban birds may actually be hindering wild nesting since falcons attract falcons. In an effort to return falcons to their historic nesting eyries in Iowa, the Iowa DNR has prioritized cliff-site releases.

Falcon production had mixed success again in 1999. On a down note, the Des Moines pair did not produce any young. The American Republic Insurance Building, where the birds nest, was getting a new roof. Rainy weather pushed construction into peak nesting time, causing too much disturbance for the breeding adults. Cedar Rapids was still a production stronghold with 3 young fledging in 1999. On a positive note, 1999 produced Iowa's third nesting falcon pair at a power smokestack in Lansing. The adults, both from Minnesota successfully produced 3 young ( $1 \mathrm{~F}, 2 \mathrm{M}$ ). Falcons have been sighted in Mason City, but no nest attempts were documented.

Release efforts continued in Iowa during 1999. Louisa released 8 birds in their second release year. The Raptor Resource Project, headed by Bob Anderson, was awarded a grant by the Iowa DNR to continue release efforts at Effigy Mounds National Monument. He released 9 falcons in 1999. Bob was also granted a FWS permit to take chicks from
smokestack nests and release them at cliff sites along the Mississippi River. A new cliff release site was added in 1999. This site, at Eagle Point Park in Dubuque, is also along the Mississippi River. Two rock-lined hack boxes were placed on a bluff overlooking the river. Volunteers released 21 falcon chicks ( $5 \mathrm{~F}, 16 \mathrm{M}$ ) in 1999 from this site.

## 2000

In 2000, for the first time in at least 3 decades, wild peregrines were produced on Mississippi River cliffs. At Queen's Bluff, in southeastern Minnesota, 1 young fledged successfully from parents which had been released in Iowa. The female was hacked from Mason City in 1998, and the male was hacked from Effigy Mounds in 1998. In all, there were 5 pairs of peregrines at cliff-sites along the Mississippi River. Thanks to efforts by Bob Anderson, the same pair that nested in 1999 in a nest-box at the Alliant Energy power plant smokestack near Lansing, now nested in a nest-box at a nearby cliff, where peregrines historically nested. They fledged 4 young ( $3 \mathrm{M}, 1 \mathrm{~F}$ ), but the young female died post fledging. It is worth noting that, according to Bud Tordoff (Tordoff et al 2000), "these were the first young peregrines known to fledge from a cliff nest in the Mississippi River valley since the extirpation of the original population by DDT in the 1950s and 1960s."

Urban nest sites were also successful in 2000. At the American Republic Building in Des Moines, 9-yearold female 13R, nesting here for the eighth year, paired again with 10 -year-old male 93T, his seventh year at the site. They produced 4 eggs and fledged 2 male young. In Cedar Rapids at the Firstar Bank nest site, a 2-year-old female, *S/*5
(fledged in Des Moines in 1998) replaced female R49. She mated with 11-year-old male 64X, here for the eighth year. They produced 4 eggs and fledged 4 young (3M,1F). Besides the 3 successful nests, there was also a peregrine pair reported in April at the smokestack nest box at the Louisa Mid-American power plant. Also reported was a 1999 Louisa released male (wearing black/green band) frequenting the Mid-American Energy Co. building in Davenport, and a peregrine with a gold band on the right leg and a red/black band on the left leg was reported in Burlington on July 1 by Conservation Officer, Don Simonson.

Mississippi River peregrine releases continued in 2000, with 19 falcons hacked at the Dubuque cliff site and 6 male peregrines hacked at the Louisa power plant site. All told, there were 164 peregrines hacked from Iowa release sites from 1989-2002. Eighty-four of these birds were released along the Mississippi River, and 62 peregrines were released off limestone bluffs.

## 2001

Year 2001 saw 5 Iowa peregrine territories. The same returning nesting pairs were identified at Des Moines, Cedar Rapids, and Lansing. The Des Moines pair produced 4 eggs and fledged 3 young ( $2 \mathrm{M}, 1 \mathrm{~F}$ ). The young female later died after colliding with a window. There were 3 eggs laid and 3 young females fledged at Cedar Rapids. The Lansing pair attempted to nest unsuccessfully on a cliff, and finally laid 4 eggs (which did not hatch) in a nest box. An unidentified pair of peregrines attempted to nest beneath the Centennial Bridge in Davenport. The female is a sub-adult wearing a black/green band, and it is not known if the male is banded. Young falcons were
heard food-begging beneath the bridge, but it is not known if any young fledged successfully (unverified report indicated one). A fifth pair of falcons held a nesting territory at the Louisa generating plant smokestack nest-box. The female hatched in 1999 from a smokestack box in Minneapolis, and the male has not been identified. The stage is set for 5 nesting pairs in 2002.

## 2002

In 2002 six falcon territories were reported with five sites successfully fledging young. At Cedar Rapids four-year-old female $* S / * 5$, nesting here for the third time, and thirteen-year-old male 64X (identified previously as 64 T ), here for the tenth year, produced four eggs, hatched three and fledged two females and a male.

The Des Moines pair once again laid three eggs on the east side of the American Republic Insurance bldg. However, the eggs disappeared as hatch date drew near. In late June an egg was discovered on the west side of building which hatched. A lone male was banded July 30 and successfully fledged in early August.

The Lansing cliff site was active in 2002 where the same pair successfully fledged two young, a male and a female. The adult female X/*D, fledged in 1998 at NSP Sherco, Becker, Minnesota and here for the first time, paired with five-year-old male $* \mathrm{~T} / \mathrm{M}$, nesting here for the fourth year. The falcon box on the bluff, across from the Alliant Energy plant placed by Bob Anderson was a suitable backdrop as historic falcon banders gathered to assist and witness event. It had been 44 years since Dan Berger, Jack Oar, Jim Grier, Jack Oberg, Dave Seal, and Chuck Sindelar banded falcons at historic eyries. This year they were assisted by Dave

Kester, banding two young.
In the Quad Cities the pair that previously occupied the Centennial Bridge nested in a falcon box placed by falconer, Tom Deckert. Three-year-old female 8/*E, hacked in 1999 at Muncie, Indiana paired with three-year-old male P/D, hacked in 1999 at Dubuque, Iowa. The MidAmerican Insurance building hosted three young, two females and a male in downtown Davenport. All successfully fledged with minimal intervention from humans.

A new falcon site came on line this year. A box affixed to the smokestack of the Louisa Generating Station near Muscatine was used. The female Z/V fledged in 1999 at NSP Riverside, Minneapolis, Minnesota. The tiercel has not been identified. One young male successfully fledged.

A sixth falcon territory occurred at the Holnam Cement Plant at Mason City. Falconer Lowell Washburn who hacked 25 young from the site between 1996 1998, reported a male was seen intermittently throughout the summer.

Also in 2002 eight young falcons were hacked at the Duane Arnold nuclear facility near Palo, Iowa. Bob Anderson with Raptor Research Project coordinated the placement of four young. Meanwhile four young at a smokestack box near Alma, Minnesota were stranded when an untimely death of the adult male occurred at that site. Plus, the female was discovered injured and unable to provide for young. The four were relocated to the Palo site and all eight successfully fledged.

## 2003

In 2003 there were seven territories in Iowa. Mason City territory at Holnam Plant was inactive, but two new territories
occurred in Iowa. Falcon activity was noted at nestbox at Alliant Plant near Chillicothe in Wapello Co. An adult peregrine was observed and a scrap was created in nestbox. At Quad Cities under I-80 bridge, a fledgling falcon was photographed and according to falconer Lowell Washburn an eyrie was presumed to have occurred under bridge. Adults were not identified at either site.

At Des Moines same adults fledged four young from second, NW alcove of American Republic building. At Cedar Rapids same adults fledged four young. At Louisa female $\mathrm{Z} / \mathrm{V}$ and unknown male fledged three young.

Near Lansing the wild pair attempted to nest on a natural ledge. Two young hatched but had disappeared by banding time. Falconers Bob Anderson and Dave Kester believed raccoon predation destroyed nest. Raccoon sign was observed in area and access by land was possible.

Quad Cities female $8 / * \mathrm{E}$ and unidentified male produced four young under Centennial bridge. Young were relocated to natural bluff near Bluffton and hacked by Bob Anderson. All four survived and were observed throughout summer.

Iowa falcons produced at least 16 young this year making it a banner year for falcon production.
2004
In 2004, Bob Anderson reported the pair at Lansing cliff, Allamakee County, hatched young but none were present at banding. A second, wild nesting pair was reported downstream by Dave Kester, on a Mississippi River cliff at Waukon Jct., Allamakee County. There were 2 eggs but no young produced. Female at this site was identified as Lora ( $48 / E$ ), hatched at Xcel Energy, Monticello, MN in 2003.

Male is two-year-old 19/M Dairyland Cooperative at Alma, Wisconsin 2002. Anderson believed only male was incubating.

A scrape was present at nest box on smokestack at Alliant Energy Plant at Chillicothe, Wapello County, but no young produced. Two unidentified peregrines occupied site.

Danny Akers, a reliable birder, reported a peregrine pair copulating about one mile southwest of Guttenberg, Clayton County, on April 18, but despite subsequent searches in the area, no eyrie was discovered.

At state Capitol bldg in Des Moines female 39/E, NSP Riverside, Minneapolis 2003, has paired with 93T and is actively defending site from intruders.

At American Republic Insurance bldg. at Des Moines, Polk Co. Iowa, female $8 / * \mathrm{~T}$ (produced three young) (Colonnade bldg. 2002) here for her first nesting attempt paired with fourteen-yearold male 93 T (produced 27 young), his twelfth year at this site. Four eggs were laid and three males fledged. One immature male, $\mathrm{D} / 06$, was retrieved dead from collision with Ruan bldg. in July.

At Louisa Generating Plant, Louisa County, Jim Haack, Mid-American Energy, reports that five-year-old female Murphy Z/V(produced eight young), here for fourth year, and an unidentified male fledged four, three males and a female. Female 62/D recently was trapped inside a building and died of apparent heat exhaustion.

At US Bank bldg at Cedar Rapids, Linn Co. Iowa, six-year-old female *S/ *5 (produced 13 young) nesting here for fifth time and 13 year-old male 64X (produced 38 ), here for $12^{\text {th }}$ year, produced four eggs, hatched four, and fledged three, one male
and two females. Female 63/D was found dead. It was feared no young survived at this site as shortly after fledging, adults were sighted repeatedly but no young were seen.

At Davenport, Scott County, a pair once again nested at Centennial Bridge on eastern section of middle span. Three young were reported before fledging, but neither adult was identified. Also, no activity was reported at 2003 territory at I80 Bridge near Bettendorf.

It appears there is a new territory at Burlington, Des Moines County, beneath another Mississippi River Bridge. Former falconer, Lee Eberly, reported at least one, and possibly two peregrines were seen flying to and from under the bridge in mid-June, and vocalizations were heard 4 or 5 times. There has been peregrine activity noted at this site in the past. No peregrines were identified, and it is unknown if there was an active nest.

In summary, young fledged was down from 16 in 2003 to 13 in 2004 at four successful sites. There was evidence of peregrine territorial activity at ten sites.

## 2005

In 2005 ten territories had seven successful fledgings with 21 young produced. At Firstar Bank (US Bank), Cedar Rapids, Linn County, Iowa, Jodeane Cancilla, Macbride Raptor Project, reports that seven-year-old female *S/*5 (produced 16 young), nesting here for the sixth year, and two-year-old male 78/E (produced 3), here for his first nesting, produced four eggs, hatched all four, and fledged three young, two males and a female.

American Republic, Des Moines, Polk County, Iowa. 15-year-old male 93T (31 young), his 13th year at this site, paired for the second year with four-year-
old female Ellie b/g 8/*T, fledged in 2001 at Colonnade, Minneapolis, Minnesota. They produced four eggs, four were banded, and fledged three young, two females and one male. One male was found dead, having fallen from eyrie. On July 22 , female $8 / * \mathrm{~T}$ was found with a wing injury that precludes further flying, although she lives on in captivity. Male 93 T has sired 31 young in his long career here.

MidAmerican Energy Corporate Headquarters, Davenport, Scott County, Iowa. Dave Sebben reports two six-yearolds, female $8 / *$ E, fledged at Muncie, Indiana, in 1999, paired with male P/D, fledged at Dubuque, Iowa, in 1999, produced one young. It was banded but died when hit by a car after fledging.

At Louisa, Louisa County, Iowa, Jim Haack, MidAmerica Energy, reports that an unidentified female and an unidentified male, both banded, fledged four young, two males and two females. This is the fourth year of successful nesting at this site.

Leo's Bluff, Waukon Junction, Allamakee County, Iowa. This is second year for this cliff site. Dave Kester and Bob Anderson report that two-year-old female Lora 48/E paired with three-yearold Brady 19/M, both here for the second year, and nested a half mile upstream from the 2004 site. They fledged two young, one each sex, from a cliff with no nest box, the first such cliff nest in Iowa in over 40 years.

Alliant Energy Lansing / Lansing cliff, Lansing, Allamakee County, Iowa. Bob Anderson, Raptor Resource Project, and Dave Kester report that an unidentified adult female with a $\mathrm{b} / \mathrm{r}$ band paired with eight-year-old male Alpha *T/M (produced 14 young), nesting here for the seventh year. The site has had an
interesting history. Falcons were first attracted to nest in a box on a nearby stack, where they fledged young in two seasons. The stack box was then removed and a box placed on the nearby cliff. Young were fledged in 2002. However, in 2003 and 2004, the falcons used a ledge instead of the box and lost their young to raccoon predation. This year, Kester and Anderson placed a new box on the stack, from which five young peregrines were fledged, three males and two females.

Alliant Energy Plant, Chillicothe, Wapello County, Iowa, Judi Johnson reports six-year-old female Z/V (produced 10 at Louisa and Chillicothe) and an unidentified male, judged by plumage to be two years old, produced four eggs and fledged two young. Female Z/V has relocated to this site from Louisa Generating Plant.

I80 Bridge, Quad Cities, Scott County, Iowa, had peregrine activity again this year. An adult pair is on site, but no young were found. A nest tray was installed under the bridge on Iowa side of center span of bridge. This bridge is 12 miles upstream from Centennial Bridge.

Mississippi bridge, Burlington, Des Moines County, Iowa. John Rutenbeck reports seeing and hearing two peregrines flying under the bridge in midJune. Peregrine activity has been noted here in past years. There was no proof of a nest this year.

State Capitol, Des Moines, Polk
County, Iowa, female Fast Track b/g 39/E, fledged in 2003 at NSP Riverside, Minneapolis, Minnesota, here in 2004 and early spring this year, was not seen through the nesting season. Adult male, T93, from downtown nest site has been soaring and perching on west side of Capitol, throughout summer.

Seven successful sites produced 21 young in 2005 . There were three additional sites with peregrine pairs for a total of ten territories this year.

There were some downturns in Iowa's peregrine population in 2006. However there were ten territories reported and five successful sites that produced eleven young. At Leo's Bluff near Waukon Junction, IA, both of the adult falcons and their young mysteriously disappeared according to bob Anderson. When he and Dave Kester rappelled into the eyrie, one pipped egg and fragments from three other eggs that indicated a normal hatch were discovered. However, there were no eyas falcons or defending adults. Other cliffs in that area of the river were searched on several occasions without finding either of the adult falcons. This is very strange and researchers are at a loss to explain what could have happened.

The adult falcons at the Lansing, IA power plant moved back to the nearby cliff this year, most probably due to a major construction project that took place near the stack. In past seasons, these falcons have lost their young around ten days of age to raccoons at this ledge. On 5/17/06, a large contingency of volunteers met at this cliff to initiate efforts to repel raccoons from the ledge site. However, they were too late. One set of raccoon tracks and eggshell fragments were discovered at the eyrie.

Another disappointment occurred in Des Moines where an unidentified female laid eggs at American Republic Insurance bldg. onto cold concrete. Four eggs were discovered and pea gravel added under them but they did not hatch.

On a brighter note at Cedar Rapids US Bank bldg. female $* S / 5 *$ here for eighth year (produced 20 young) and three-year-old
male 78/E (produced seven young) here for second year. Pair produced four young three males and one female.

At MidAmerican Energy Corporate Headquarters, Davenport, Scott County, Iowa. Dave Sebben reports two seven-year-olds, female $8 / *$ E, fledged at Muncie, Indiana, in 1999, paired with male P/D, fledged at Dubuque, Iowa, in 1999, produced two young.

At Louisa Generating Station, Jim Haack, MidAmerican Energy, reports that an unidentified female and an unidentified male, both banded, fledged two females and one male. There was one dead young in box. This is the fifth year of successful nesting at this site.

Alliant Energy Plant, Chillicothe, Wapello County, Iowa, Judi Johnson reports seven-year-old female Z/V (produced 10 at Louisa and Chillicothe) and an unidentified male and fledged one young.

At Great River Bridge local birder, Hal Geren, reported two adult and one young throughout July.

At I 280 Bridge at Quad Cities, local birder Kelly McKay reported pair of falcons on west pier (Iowa side) of bridge. Two eggs on concrete were discovered and placed in a nest tray with pea gravel. There was no further activity reported at this site.

At I 80 bridge in Quad Cities a pair of peregrines were defending the bridge but no eggs were discovered. Nest tray on Iowa side of bridge had not been used.

In summary there were ten territories with five successful pairs and eleven young produced in 2006.

## 2007

Spring 2007 held great promise for peregrine nesting in Iowa. A definition of
success might include as many wildproduced young in a year that were hacked in any given year, since project began in 1989. In 1999 at Eagle Point Park in Dubuque, 21 peregrines were released by Lowell Washburn, Tom Deckert and Dubuque College. This year twelve territories with eight successful nests produced 23 young.

In Des Moines four young were produced at American Republic Insurance bldg. (37 young since '93) New male at this site is $63 / \mathrm{B}$, (Woodman Tower , Omaha, NE. '04)(four young '07). There is a second territory at State Capitol.

In Cedar Rapids a brood of five young were reported by Theresa Chapel at USBank (50 young since '93). Female *S/5* (Des Moines, IA '98) here for ninth year (produced 25 young) and four-yearold male 78/E (Kokomo, IN. '03) here for third year (produced 12 young) produced five young, all males.

At Lansing cliff (14 young since '99), Bob Anderson boarded up the power plant nest box and installed a cliff nest box here on $3 / 30 / 07$. Raccoon predation has been a problem at this location, but it was believed the box would provide a successful nest. Raccoon predation occurred again this year.

At Leo's Bluff near Waukon Jct. (four young since '05) Bob Anderson reported that last year falcons hatched one egg successfully, but the entire family mysteriously disappeared in mid-May. This year, the nest was successful with two young. Adult female 66/A (St. Louis '05) and male is unbanded. First nested here 2004.

At Clinton, Iowa, (one young '07) unidentified pair produced one young at new site. Site is ML Kapp Generating Station with Alliant Energy. This site is located at southern extent of historic
peregrine nesting range along Mississippi flyway in Iowa.

At I 80 Bridge unidentified pair defended territory, but no eyrie or young detected. Nest tray had not been used and is now located on upstream side on Illinois side of channel.

At MidAmerican HQ (12 young since '02) in Quad Cities same eight-yearold pair 8/*E (Muncie, IN '99) and P/D (Dubuque, IA '99) here for sixth year (two on Centennial Bridge) laid four eggs in rain gutter. Eggs were placed in nest tray but did not hatch. Female recycled and laid four eggs in nest box, but did not successfully hatch.

At I 280 bridge (four young '07) near Quad Cities unidentified pair produced four young at this new site. Young were banded by Jodeane Cancilla of Macbride Raptor Project with assistance from Illinois DOT officials. At Louisa Generating Station (19 young since '02) Jim Haack reported four young successfully fledged from 06/A female (St. Louis, MO. '05) and unidentified male for sixth year.

At Burlington, Great River Bridge (at least two young since '04) an unidentified pair, here for fourth year fledged at least one young.

At Chillicothe (five young since '05), Ottumwa Generating Station with Alliant Energy, Judi Johnson reports eight year-old female Z/V (NSP Riverside, Mpls. MN. '99) (produced 12 at Louisa and Chillicothe) and an unidentified male fledged two young.

In summary twelve territorial pairs provided eight successful nests with 23 young produced in 2007.

## 2008

Spring 2008 began inauspiciously enough, but climate conditions resulted in a tough
year for some peregrine pairs in Iowa. This year thirteen territories with eight successful nests produced 20 young.

In Des Moines three young were produced at American Republic Insurance bldg. (40 young since '93) Male at this site is $63 / \mathrm{B}$, (Woodman Tower, Omaha, NE. '04)(seven young '07). Female is unbanded.

A second territory at State Capitol produced two young. Female 39/E (NSP Riverside Plant, Minneapolis MN) has been at Capitol since 2003. Male is unbanded.

In Cedar Rapids a brood of two young were reported by Theresa Chapel at USBank (52 young since '93). Female *S/5* (Des Moines, IA '98) here for tenth year (produced 27 young) and five-yearold male 78/E (Kokomo, IN. '03) here for fourth year (produced 14 young).

At Lansing cliff (17 young since '01), Bob Anderson reports falcon pair back in Alliant Energy smokestack box and fledged three.

At Waukon Jct. (seven young since '04) Bob Anderson reported that pair relocated up stream to Gitta's Bluff. Nest was successful with three young. Adult female *K/*W (John Latsch Park, MN '06) and male is unbanded.

At Clinton, Iowa, (one young '07) unidentified pair produced no young at this site. Site is ML Kapp Generating Station with Alliant Energy. This site is located at southern extent of historic peregrine nesting range along Mississippi flyway in Iowa.

At I 80 Bridge unidentified pair defended territory, but no eyrie or young detected. Nest tray had not been used and is now located on upstream side on Illinois side of channel.

At MidAmerican HQ (13 young since '02) in Quad Cities same nine-year-
old pair 8/*E (Muncie, IN '99) and P/D (Dubuque, IA '99) here for seventh year (two on Centennial Bridge) laid three eggs in nest box. One young fledged.

At I 280 bridge (four young '07) near Quad Cities unidentified pair produced nested on Illinois side of bridge. Flood conditions prevented exploring this site in '08.

At Louisa Generating Station (23 young since '02) Jim Haack reported four young successfully fledged from 06/A female (St. Louis, MO. '05) and unidentified male for seventh year.

At Burlington, Great River Bridge (at least four young since '04) an unidentified pair, here for fifth year fledged two young.

At Chillicothe (four young since '05), Ottumwa Generating Station with Alliant Energy, Judi Johnson reports nine-year-old female Z/V (NSP Riverside, Mpls. MN. '99) (produced 12 at Louisa and Chillicothe) and an unidentified male were unsuccessful. Three eggs were discovered June 13, but area was subjected to violent storms later in the month.

There is a new pair occupying Agri-Bunge grain elevator at McGregor, Iowa. Female is a brown bird immature.

In summary thirteen territorial pairs provided eight successful nests with 20 young produced in 2008.

## 2009

Spring 2009 heralded the year Peregrine Falcons were upgraded from Endangered to a Species of Special Concern status in Iowa. This year thirteen territories with nine successful nests produced 25 young.

In Des Moines four young were produced at American Republic Insurance bldg. (44 young since '93) Male at this site is $63 / \mathrm{B}$, (Woodman Tower , Omaha,

NE. '04)(11 young '07) Female is 39 E (NSP Riverside plant ' 03 ) here for first year (produced six young two at capitol in '08).

A second territory at State Capitol produced four young. Female (six young) and male are unbanded (four young).

In Cedar Rapids a brood of one young was reported by Theresa Chapel at USBank (53 young since '93). Female *S/5* (Des Moines, IA '98) here for eleventh year (produced 28 young) and six-year-old male 78/E (Kokomo, IN. '03) here for fifth year (produced 15 young).

At Lansing cliff (20 young since '01), Bob Anderson reports falcon pair back in Alliant Energy smokestack box and fledged three.

At Waukon Jct. (seven young since '04) Bob Anderson reported that pair relocated back to Leo's Bluff. Nest was unsuccessful. Adult female $* \mathrm{~K} / * \mathrm{~W}$ (John Latsch Park, MN '06) and male is unbanded.

At Clinton, Iowa, (three young '07) unidentified pair produced two young at this site. Site is ML Kapp Generating Station with Alliant Energy. 46D was photographed at ADM and is possibly at ML Kapp. This site is located at southern extent of historic peregrine nesting range along Mississippi flyway in Iowa.

At I 80 Bridge unidentified pair defended territory, but no eyrie or young detected. Nest tray had not been used and is now located on upstream side on Illinois side of channel.

At MidAmerican HQ (15 young since '02) in Quad Cities same ten-yearold pair $8 / *$ E (Muncie, IN '99) and P/D (Dubuque, IA '99) here for eighth year (two on Centennial Bridge) laid three eggs in nest box. Two young fledged.

At I 280 bridge (four young '07) near Quad Cities unidentified pair nested on Illinois side of bridge.

At Louisa Generating Station (27 young since '02) Jim Haack reported four young successfully fledged from 06/A female (St. Louis, MO. '05) and unidentified male for eighth year.

At Burlington, Great River Bridge (at least four young since '04) an unidentified pair, here for sixth year fledged one young.

At Chillicothe (nine young since '05), Ottumwa Generating Station with Alliant Energy, Judi Johnson reports ten-year-old female Z/V (NSP Riverside, Mpls. MN. '99) (produced 16 at Louisa and Chillicothe) and an unidentified male were successful. Four young fledged.

In summary thirteen territorial pairs provided nine successful nests with 25 young produced in 2009.

## 2010

Spring 2010 was the year Peregrine Falcons were considered a Species of Special Concern in Iowa and no longer endangered. It should be noted that nesting pair on I 280 bridge near Davenport have located on the Illinois side the last three years and are no longer included in Iowa data base. This year fourteen territories with ten successful nests produced 21 young.

In Des Moines two young were produced at American Republic Insurance bldg. (46 young since '93) Male at this site is $63 / \mathrm{B}$, (Woodman Tower, Omaha, NE. '04)(13 young '07) Female is 39 E (NSP Riverside plant ' 03 ) here for second year (produced eight young, two at Capitol in '08).

A second territory at State Capitol produced one young. Unbanded female (seven young) and male 39/A (American

Republic '08) here for first year were successful above east portico.

In Cedar Rapids a brood of four young was reported by Theresa Chapel at USBank (57 young since '93). Female *S/5* (Des Moines, IA '98) here for twelth (produced 32 young) and seven-year-old male 78/E (Kokomo, IN. '03) here for sixth year (produced 19 young).

At Lansing cliff (22 young since '01), Bob Anderson reports falcon pair back in Alliant Energy smokestack box and fledged two.

At Waukon Jct. (seven young since '04) Bob Anderson reported that pair relocated back to Leo's Bluff. Nest was unsuccessful. Adult female $* \mathrm{~K} / * \mathrm{~W}$ (John Latsch Park, MN '06) and male is unbanded.

At MacGregor Bob Anderson reports Agri Bunge Elevator has unidentified pair. Thre young were produced.

At Clinton, Iowa, (three young ${ }^{\prime} 07$ ) unidentified pair were not successful at this site. Site is ML Kapp Generating Station with Alliant Energy. 46D was photographed at ADM and is possibly at ML Kapp. This site is located at southern extent of historic peregrine nesting range along Mississippi flyway in Iowa.

At ADM plant in Clinton, new nesting pair produced three males. Female is $35 / \mathrm{M}$ and female is $83 / \mathrm{M}$ (Cedar Rapids '03)

At I 80 Bridge unidentified pair defended territory, but no eyrie or young detected. This bridge was under reconstruction this year but pair did not relocate to nest box on MidAmerican Riverside smokestack just downstream.

At MidAmerican HQ (18 young since '02) in Quad Cities same eleven-year-old pair 8/*E (Muncie, IN '99) and P/D (Dubuque, IA '99) here for ninth year
(two on Centennial Bridge) laid four eggs in nest box. Three young fledged.

At I 280 bridge (four young '07) near Quad Cities unidentified pair nested on Illinois side of bridge. We will no longer include this pair with Iowa totals.

At Louisa Generating Station (28 young since '02) Jim Haack reported one young successfully fledged from 06/A female (St. Louis, MO. '05) and unidentified male for ninth year. An earlier hatch of three young had disappeared by June 11. A new nest site at the plant near area that was used for releases produced one young.

At Burlington, Great River Bridge (at least five young since '04) an unidentified pair, here for seventh year fledged one young.

At Chillicothe (11 young since '05), Ottumwa Generating Station with Alliant Energy, Judi Johnson reports eleven- year-old female Z/V (NSP Riverside, Mpls. MN. '99) (produced 18 at Louisa and Chillicothe) and an unidentified male were successful. two young fledged.

There were two new bridge pairs to be aware of at Dubuque and Muscatine this year. At Dead Cow bluff near Lansing bob Anderson reported dawn from young but no falcons in June.

In summary fourteen territorial pairs provided ten successful nests with 21 young produced in 2010.

## 2011

Spring 2011 had intense weather events. Most notably adverse conditions were blamed for no production from falcon pairs in NE Iowa cliff region. It should be noted that nesting pair on I 280 bridge near Davenport will be included in the Iowa data base. This year 16
territories with nine successful pairs produced 22 young.

In Des Moines four young were produced at American Republic Insurance bldg. (50 young since '93). Male at this site is 63 B , (Woodman Tower, Omaha, NE. '04)(17 young '07) Female is 39E (NSP Riverside plant '03) here for third year (produced 12 young, two at Capitol in ' 08 ).

A second territory at State Capitol (eight young since 2009) produced two young. Unbanded female (six young) and male 39/A (American Republic '08) here for second first year (six young '10) were successful above east portico.

In Cedar Rapids a brood of four young was reported by Theresa Chapel at USBank (61 young since '93). Female *S/5* (Des Moines, IA '98) here for thirteenth (produced 36 young) and eight-year-old male 78/E (Kokomo, IN. '03) here for seventh year (produced 23 young).

At Guider's Bluff aka Dead Cow Bluff (unidentified active pair since 2010) was not successful according to Bob Anderson.

At Lansing Cliff aka Achaflaya
Bluff (22 young since '01), Bob Anderson reports falcon pair on cliff but were unsuccessful.

At Waukon Jct. (seven young since '04) Bob Anderson reported that pair relocated back to Leo's Bluff. Nest was unsuccessful. Adult female $* \mathrm{~K} / * \mathrm{~W}$ (John Latsch Park, MN '06) and male is unbanded.

At MacGregor reports Bunge
Elevator (Three young since 2010) Bob Anderson reported unidentified pair was unsuccessful.

At Dubuque Bridge (Two young since 2010) Roger Scholbrock reports two young fledged from unidentified pair.

At Clinton, Iowa, (Three young since '07) unidentified pair were not successful at this site. Site is ML Kapp Generating Station with Alliant Energy. 46 D was photographed at ADM and is possibly at ML Kapp. This site is located at southern extent of historic peregrine nesting range along Mississippi flyway in Iowa.

At ADM plant in Clinton (Five young since ' 10 ), nesting pair produced two males. Female is $35 / \mathrm{M}$ (Kansas City 2005) (Five young since '10) and female is $83 / \mathrm{M}$ (Cedar Rapids '03)(Five young since ' 10 ).

At I 80 Bridge unidentified pair defended territory, but no eyrie or young detected.

At MidAmerican HQ (19 young since '02) in Quad Cities same twelve-year-old pair 8/*E (Muncie, IN '99) and P/D (Dubuque, IA '99) here for tenth year (two on Centennial Bridge) laid three eggs in nest box. One young fledged.

At I 280 bridge (five young '07) near Quad Cities unidentified pair nested on Illinois side of bridge. Iowa will record data at this site.

At Louisa Generating Station (28 young since '02) Jim Haack reported no young successfully fledged. Female06/A female (St. Louis, MO. '05) and unidentified male for tenth year.

At Burlington, Great River Bridge (at least five young since '04) an unidentified pair, here for eigth year fledged two young.

At Chillicothe (14 young since '05), Ottumwa Generating Station with Alliant Energy, Judi Johnson reports new pair five year old female N23 (Sharon Cargill Plant Jefferson Co. WI 2006)(three young since 2011) and male 26/B (Am. Rep. Des Moines 2009) (three young since 2011). Three young fledged.

In summary 16 territorial pairs provided nine successful nests with 22 young produced in 2011.

## 2012

Spring 2012 came early from very mild winter season. It should be noted that nesting pair on I 280 bridge near Davenport have located on the Illinois side the last five years and are no longer included in Iowa data base. This year 15 territories with 13 successful nests produced 34 young.

In Des Moines three young were produced at American Republic Insurance bldg. (49 young since '93) Male at this site is 63/B, (Woodman Tower, Omaha, NE.' 04 )(16 young '07) Female is 39E (NSP Riverside plant ' 03 ) here for second year (produced 11 young, two at Capitol in ' 08 ).

A second territory at State Capitol produced one young. Unbanded female (eight young) and male 39/A (American Republic '08) here for third year were successful above east portico.

In Cedar Rapids a brood of three young was reported by Theresa Chapel at USBank (60 young since '93). Female *S/5* (Des Moines, IA '98) here for fourteenth year (produced 35 young), and nine-year-old male 78/E (Kokomo, IN. '03), here for eighth year (produced 22 young).

A new site at Aggie's Bluff two miles upstream from Lansing an unidentified pair produced four young.

At Lansing cliff (26 young since '01), Bob Anderson reports falcon pair back in Alliant Energy smokestack box and fledged four.

At Waukon Jct. (seven young since '04) Bob Anderson reported that pair relocated back to Leo's Bluff. Nest was unsuccessful. Adult female $* \mathrm{~K} / * \mathrm{~W}$
(John Latsch Park, MN '06) and male is unbanded.

At MacGregor Bob Anderson reports Bunge America Elevator has unidentified pair. Three young were produced.

At Dubuque Wisconsin Bridge Roger Scholberg unidentified pair here for third reports one young produced from.

At Clinton, Iowa, (six young '07) unidentified pair were successful at this site with three young. Site is ML Kapp Generating Station with Alliant Energy. 46 D was photographed at ADM and is possibly at ML Kapp. This site is located at southern extent of historic peregrine nesting range along Mississippi flyway in Iowa.

At ADM plant in Clinton, nesting pair produced two (seven young since 2010.) Female is $35 / \mathrm{M}$ and female is 83/M (Cedar Rapids '03)

At I 80 Bridge unidentified pair defended territory, but no eyrie or young detected.

At MidAmerican HQ (21 young since '02) in Quad Cities same thirteen-year-old pair 8/*E (Muncie, IN '99) and P/D (Dubuque, IA '99) here for 11th year (two on Centennial Bridge) laid four eggs in nest box. Three young fledged.

At I 280 bridge (four young '07) near Quad Cities unidentified pair nested on Illinois side of bridge. We will no longer include this pair with Iowa totals.

At Louisa Generating Station (30 young since '02) Jim Haack reported two young successfully fledged from 06/A female (St. Louis, MO. '05) and unidentified male for eleventh year. A new nest site at the plant near area that was used for releases produced one young.

At Burlington, Great River Bridge (at least seven young since '04) an
unidentified pair, here for ninth year fledged one young.

At Chillicothe ( 15 young since '05), Ottumwa Generating Station with Alliant Energy, Judi Johnson reports eleven- year-old female Z/V (NSP Riverside, Mpls. MN. ‘99) (produced 22 at Louisa and Chillicothe) and an unidentified male were successful - four young fledged.

In summary 15 territorial pairs provided 13 successful nests with 34 young produced in 2012.

## 2013

Spring 2013 came late as conditions were very wet and cold. There was snow in the northern half of the state on May 3. It should be noted that nesting pair on I 280 bridge near Davenport have located on the Illinois side the last five years and are no longer included in Iowa data base. This year 15 territories with 14 successful nests produced 32 young.

In Des Moines two young were produced at American Republic Insurance bldg. (51 young since '93) Male at this site is 63/B, (Woodman Tower, Omaha, NE.' 04 )(18 young '07) Female is 39 E (NSP Riverside plant '03) here for third year (produced 13 young, two at Capitol in ' 08 ).

A second territory at State Capitol (11 young since '08) produced three young. Unbanded female (9 young) and male 39/A (American Republic '08) here for third year were successful above east portico. Male was injured and died so there will be a replacement male at this site in 2014.

In Cedar Rapids a brood of three young was reported by Theresa Chapel at USBank (63 young since '93). Female *S/5* (Des Moines, IA '98) here for
fifteenth (produced 38 young) and ten-year-old male 78/E (Kokomo, IN. '03) here for ninth year (produced 25 young).

The site at Aggie's Bluff two miles upstream from Lansing an unidentified pair produced three young their second year at this site (produced seven young since 2012.)

At Lansing cliff (29 young since '99), Bob Anderson reports falcon pair back in Alliant Energy cliff box and fledged three.

At Waukon Jct. (seven young since '04) Bob Anderson reported that pair relocated back to Leo's Bluff. Nest was unsuccessful. Adult female $* \mathrm{~K} / * W$ (John Latsch Park, MN '06) and male is unbanded.

At MacGregor Bob Anderson reports Bunge America Elevator (12 young since 2008) has unidentified pair. Three young were produced.

At Dubuque Wisconsin Bridge (four young since '10) Roger Scholberg unidentified pair here for fourth year reports one young produced.

At Clinton, Iowa, (eight young ${ }^{\prime} 07$ ) unidentified pair were successful at this site with three young. Site is ML Kapp Generating Station with Alliant Energy. 46D was photographed at ADM and is possibly at ML Kapp. This site is located at southern extent of historic peregrine nesting range along Mississippi flyway in Iowa.

At ADM plant in Clinton, nesting pair produced two (nine young since 2010.) Female is $35 / \mathrm{M}$ and female is 83/M (Cedar Rapids '03)

At I 80 Bridge ( 2003) unidentified pair produced two young.

At MidAmerican HQ (22 young since '02) in Quad Cities same fourteen-year-old pair 8/*E (Muncie, IN '99) and P/D (Dubuque, IA '99) here for 12th year
(two on Centennial Bridge) laid four eggs in nest box. One young fledged.

At Louisa Generating Station (33 young since '02) Jim Haack reported young successfully from 06/A female (St. Louis, MO. '05) and unidentified male for twelfth year. Pair produced three young from smaller nest box.

At Burlington, Great River Bridge (at least eight young since '04) an unidentified pair, here for tenth year fledged one young.

At Chillicothe (17 young since '05), Ottumwa Generating Station with Alliant Energy, Judi Johnson reports female b/g N23 (six young since '12) and male b/r B26 (six young since '12) were successful - two young fledged. This is their second year.

In summary 15 territorial pairs provided 14 successful nests with 32 young produced in 2013.

## 2014

Spring 2014 held great promise for Peregrine Falcon nesting in Iowa. This year 16 territories with 13 successful nests produced 33 young.

In Des Moines two young were produced at American Enterprise (previously American Republic Insurance bldg.) (53 young since '93) Male at this site is $63 / \mathrm{B}$, (Woodman Tower, Omaha, NE.' 04 )(20 young '07) Female is 39 E (NSP Riverside plant '03) here for third year (produced 15 young, two at Capitol in ' 08 ).

A second territory at the State Capitol (14 young since ' 08 ) produced three young. Unbanded female (12 young since ' 09 ) and unbanded male (three '14) were successful. Male 39/A (American Republic '08) was injured and died from septic injury to talon.

In Cedar Rapids a brood of three young was reported by Theresa Chapel at USBank (63 young since '93). Female *S/5* (Des Moines, IA '98) here for sixteenth (produced 41 young) and ten-year-old male 78/E (Kokomo, IN. '03) here for tenth year (produced 28 young).

The site at Aggie's Bluff two miles upstream from Lansing an unidentified pair produced three young their third year at this site (produced 10 young since 2012.) Bob Anderson's Raptor Resource Project attempted to rappel to the eyrie, but it's location is not accessible. At Lansing cliff (33 young since '99), Bob Anderson reports falcon pair back in Alliant Energy cliff box and fledged four.

At Waukon Jct. (seven young since '04) Bob Anderson reported that pair relocated back to Leo's Bluff. Nest was unsuccessful. Adult female $* \mathrm{~K} / * \mathrm{~W}$ (John Latsch Park, MN '06) and male is unbanded.

At MacGregor Bob Anderson reports Bunge America Elevator (15 young since 2008) has unidentified pair. Three young were produced.

At Bellevue State Park, Shannon Peterson reported pair at nestbox on rock but no young fledged.

At Dubuque Wisconsin Bridge (four young since '10) Roger Scholberg reported no sign of pair. However on a bright note there is a pair at Eagle Point Park Quarry.

At Clinton, Iowa, (eight young '07) unidentified pair were successful at this site with two young. Site is ML Kapp Generating Station with Alliant Energy. 46 D was photographed at ADM and is possibly at ML Kapp. This site is located at southern extent of historic peregrine nesting range along Mississippi flyway in Iowa.

At ADM plant in Clinton, nesting pair produced two (nine young since 2010.) Female is $35 / \mathrm{M}$ and female is 83/M (Cedar Rapids '03)

At I 80 Bridge (2003) unidentified pair produced one young.

At MidAmerican HQ (21 young since '02) in Quad Cities same fifteen-year-old pair 8/*E (Muncie, IN '99) and P/D (Dubuque, IA '99) here for 13th year (two on Centennial Bridge) laid four eggs in nest box. One young fledged.

At Louisa Generating Station (33 young since '02) Jim Haack reported young successfully from 06/A female (St. Louis, MO. '05) and unidentified male for twelfth year. Pair produced three young from smaller nest box.

At Burlington, Great River Bridge (at least ten young since '04) an unidentified pair, here for eleventh year fledged two young. At Chillicothe (21 young since '05), Ottumwa Generating Station with Alliant Energy, Judi Johnson reports female $\mathrm{b} / \mathrm{g}$ N23 (eight young since ' 12 ) and male $\mathrm{b} / \mathrm{r}$ B26 (ten young since '12)
were successful - four young fledged. This is their third year.

In summary 16 territorial pairs provided 13 successful nests with 33 young produced in 2014.

A Falcon River Trip is planned for May 1-2, 2015 once again at Harper's Ferry in NE Iowa. Watch for further details in upcoming events in the Newsletter.

Young Peregrine falcons produced from known lowa nesting pairs 1993 - Present.

Peregrine falcons released in lowa as part of the Midwestern Peregrine Recovery Project.

## GREATER PRAIRIE CHICKEN RESTORATION

## HISTORICAL REVIEW

Greater prairie chickens
(Tympanuchus cupido pinnatus)
commonly nested throughout Iowa from
the time of European settlement in the
mid-nineteenth century until about 1900 .
Numbers peaked about 1880 when most
of Iowa was a mosaic of small grainfields,
hayfields, pasture, and native prairie,
which provided ideal habitat conditions
(Ehresman 1996). During the late
nineteenth century, prairie chickens were
the most abundant gamebird on Iowa
prairies. Hunting and trapping them for
food and market were very important to
settlers. Bags of 25 to 50 a day were
common, and some hunters took up to 200
per day.
By 1878, Iowa lawmakers were concerned that prairie chickens were being over-harvested. The Iowa Legislature passed a law that year limiting the daily bag of prairie chickens to 25 birds per person. This is believed to be the first time that bag limits were used as a tool to regulate the harvest of game in the United States. Additional restrictions followed, and the last open season for prairie chickens in Iowa was held in 1915 (Stempel and Rodgers 1960).

As agricultural land use intensified, populations of prairie chickens started to decline. By the 1930's, most prairie chickens found in the northwestern part of the state were migrant winter flocks. By the 1950's, the only known nesting prairie chickens were in Appanoose, Wayne, and Ringgold Counties in southern Iowa. The last verified nesting prior to reintroduction attempts was in Appanoose County in 1952 (Stempel and Rodgers 1960).

## RESTORATION

## First Reintroduction

In the early 1980's, the Iowa Conservation Commission, now the Iowa Department of Natural Resources (IDNR), attempted to restore prairie chickens to west central Iowa. The IDNR negotiated with the Kansas Fish and Game Commission (KFGC), now Kansas Department of Wildlife and Parks (KDWP), to trade wild turkeys for 100 prairie chickens (Table 8.1). The release site was located in the Loess Hills east of Onawa, Monona County (Fig. 8.1). This is an area of steep to moderately rolling bluffs and hills bordering the Missouri River valley. These hills have large expanses of grassland interspersed with brush and small crop fields.

Fifty-three prairie chickens were released in 1980. Results from the first release were mixed. A large number of chickens were observed in the release area the following day; however, sightings thereafter were sporadic and often at a distance from the release area. In 1981, single birds occurred near the release area and groups of birds were reported 20 and 60 miles from the release site. No spring leks were located in the 2 years following the release, and no reproduction was reported.

In 1982, KFGC personnel decided to attempt a different trapping approach, using rocket-nets to trap chickens on the lek sites. This resulted in 48 more chickens being transported to Iowa for release at the same area in the Loess Hills. A greater effort to acclimatize the birds was made in the 1982 release. The birds were banded and put in a large holding pen with separate cells for each sex. They
were kept in pens overnight for the males and a day longer for the females. It was hoped that males would be stimulated to remain near the release site by holding the females a day longer. Taped lek calls were also played through speakers located near the pen about 45 minutes prior to releasing males. This was an attempt to induce chickens to establish a lek in the area.

Two prairie chicken broods were reported near the release site in 1982, and up to six adults were observed near the Missouri River bottom the same year. Two leks consisting of only a few displaying males were located in 1983 and 1984. Most sightings were in the heavily agricultural Missouri River valley instead of the hills where they were released. Suitable grassland habitat was lacking in the valley. Only an occasional sighting has been reported in this region since 1984, leading to the conclusion that this reintroduction effort failed (Ron Munkel, IDNR, pers. comm.).

## Second Reintroduction Attempt

1987-1989 Stockings: In 1987, the IDNR made a second restoration attempt at Ringgold Wildlife Area located two miles north of the Missouri border in Ringgold County (Fig 8.1). Wildlife personnel considered this region to be the best potential prairie chicken habitat in Iowa. In addition, the immediate vicinity was one of the last strongholds of prairie chickens in southern Iowa and northern Missouri (Christisen 1985, Stempel and Rodgers 1960). The surrounding portions of Ringgold County and adjacent Harrison County, Missouri, are cattle country, with $60 \%$ or more of the land in permanent grass. Donald Christisen (1985) concluded that the demise of prairie chickens in this area was due to heavy utilization of grasslands by livestock, resulting in poor
quality habitat. Recent years had brought some positive changes in the grasslands of the area including the restoration of around 200 ha of prairie on the Ringgold Wildlife Area.

Birds were again obtained from Kansas through a three-way trade in which IDNR supplied wild turkeys to the Michigan Department of Natural Resources (MDNR) while a MDNR crew trapped prairie chickens in Kansas for translocation to Iowa. Prairie chickens were captured in the spring with funnel traps set on booming grounds in the Flint Hills region of Kansas. Every few days the captured birds were transported to Iowa and released the next morning utilizing a soft release box and artificial lek technique, which had been successfully used in Kansas to reintroduce sharptail grouse (Rodgers 1987). A total of 254 prairie chickens were translocated to the Ringgold Wildlife Area from Kansas during 1987, 1988, and 1989 (Table 8.1).

By the spring of 1988, leks had been established at the release site and a site 15 km south in Missouri. The Missouri site was on the Dunn Ranch, a cattle ranch operated by Forrest and Maury Meadows of Bethany, Missouri. The ranch included about 500 ha of wellmanaged native prairie pasture in addition to several hundred hectares of cool season pasture. This ranch contained a major lek before the disappearance of prairie chickens in the 1960's. The lek established in 1988 was on the same site as the historic lek, and the birds using it were verified as Iowa release birds by the bands on their legs (Maury Meadows, pers. comm.).

During 1990 and 1991 reproductive conditions for gallinaceous birds were poor in this area; however, brood sightings were made each year. By

1991, prairie chickens appeared to be firmly established on Dunn Ranch, but only one lek of six males could be located in Iowa that year. The success of the reintroduction of prairie chickens to the Dunn Ranch was the bright spot of the project thus far. It was evident that reintroductions in this region could succeed.

1992-94 Stockings: An agreement with KDWP once again allowed IDNR crews to trap and translocate 100 prairie chickens a year. Instead of releasing all of the birds at one site, it was decided to release significant numbers on large grassland tracts in the region, while releasing a smaller number at the original Ringgold Wildlife Area. Birds were translocated to two new sites in 1992, Mount Ayr and Kellerton, respectively 28 and 24 km north of Ringgold (Fig. 8.1). Sites continued to shift in subsequent years and the Orient site (Adair County) was added in 1993. All of the sites contained high quality grasslands and open landscapes. Predominant land use at all three sites was a mixture of pasture, hay, and CRP.

A total of 304 prairie chickens were released in this three-year period (Table 8.1).
Subsequent Stocking: No additional stockings were anticipated following releases in 1994. However in 2001, South Dakota Game Fish and Parks (SDGFP) employees incidentally trapped three prairie chickens and offered them to IDNR. One male and two female chickens were released at the Kellerton lek in April 2001. This additional release results in a total of 561 prairie chickens translocated to Iowa since 1987.
Missouri Reintroduction: The Missouri Department of Conservation (MDC) has been reintroducing prairie chickens in
north central Missouri since 1993. Approximately 100 birds have been released each year through 1997 and again in 2000. They have released birds at eight sites located 60 to 100 km southeast of the Ringgold Wildlife Area and 10 to 40 km south of the Iowa border (Larry Mechlin, MDC, pers. comm.). Some of these birds have been spotted in Iowa over the years.

Current Restoration Attempts: In 2012 the Iowa DNR assembled an Iowa Management Plan for Greater Prairie Chickens. The plan includes a relatively detailed analysis of habitat in Ringgold County, Iowa and recommendations for managing that habitat for prairie chickens. A portion of the plan also proposes a translocation effort to bolster the diminishing population of birds.

In the short-term, the plan suggests trapping and releasing roughly 350 birds between 2012 and 2015. In early April 2012, fifty birds, 25 male and 25 female birds were trapped in Southwest Nebraska (near Imperial) and released within 24 hours on the two active lek sites in the vicinity of Kellerton in Ringgold County, IA.

In 2013, 73 birds were successfully released at two active Iowa leks as well as an additional location at Dunn Ranch in Missouri. These birds were also trapped near Imperial, NE primarily using walk-in traps on leks. The goal had been to translocate 100 birds but drought in NE during the preceding year had impacted the birds available and crews also encountered poor weather during trapping. Missouri received $45 \%$ of the birds released and Iowa received $55 \%$.

A total of 109 birds were released in Iowa and Northern Missouri in the spring of 2014. These birds were trapped in the Sandhills of Nebraska near Burwell. Sixty-four of these birds were released at
two active lek sites in Iowa (Kellerton WA and a private) and 45 were released at TNC's Dunn Ranch in Missouri. All release locations are within the Grand River Grasslands.

## BOOMING GROUND SURVEY

## Methods

Attempts have been made each spring by IDNR personnel and volunteers to locate leks and count booming males. Counts of known leks are made on sunny mornings with winds $<10 \mathrm{mph}$ throughout the month of April. In the past, lek sites were glassed or flushed to determine the number of booming males and new leks were located by driving gravel roads and stopping periodically to listen for booming. A more formalized survey was begun in 2009, using a prairie chicken habitat suitability model to establish 10 Survey Areas across 8 southern Iowa counties (Fig. 8.2). Each survey area had 15 listening points located randomly or at a known past or present lek site. As the translocation started in 2012 and staff time became limited the area surveyed was constricted to a 25 mile radius of Kellerton and this continued in 2013. In 2014 we added 2 additional routes to expand the area covered in Iowa based on dispersal data from 2013's released birds. A total of 71 listening points were surveyed once a week during the booming season (Fig. 8.2). Similar counts were done on and around the Dunn Ranch in Missouri. It is possible that some booming grounds have not been located.

## Results

2004: Only one new location was noticed this year (Table 8.2). There was a loss of three leks from 2003 to six for 2004, which is below the average to date by

21\% (Table 8.2). For the first time since reporting in 1995, only two counties are reported with active leks. Total booming males is among the lowest in record since 1997 (Table 8.2). However, males per lek continues to show steady numbers in recent years with 3.7 in 2004. Despite the large amount of spring rain in 2004, biologists still received reports of large broods. Current and prior lek locations are shown in figure 8.2.
2005: Two new lek locations were noted this year (Table 8.2). However, there was a reduction in total number of leks from six in 2004 to five this year. In 2005, there were once again 3 counties reporting active leks, which is up one county from last year. Total booming males was 24 , which also is up from 22 last year (Table 8.2). Males per lek was the highest it has been since 2000, with 4.8 males per lek seen. Weather conditions were favorable for nesting this season, and broods have been reported. Current and prior lek locations are shown in figure 8.2.
2006: One new lek location was noted this year though one previously active was observed inactive so the total number of active leks remains at five (Table 8.2). These five leks were spread across three counties which is also consistent with last year. However, the lowest number of booming males since 1996 was recorded this year with only 16 reported (Table 8.2). The average number of males per lek was 3.2. No brood sightings were reported. Current and prior lek locations are shown in figure 8.2.
2007: Four active leks were identified this year spread through 3 counties (Table 8.2). Only 15 booming males were recorded across these leks with an average of 3.75 males per lek. The largest lek is by the Kellerton viewing platform and observers on April 2, 2007 reported between 14-22 birds at a time on the lek
evenly split between male and female. No broods were spotted during summer surveys in 2007.

The number of leks has declined over the past 10 years from a high of 9 to this year's 4 . The number of booming males has declined as well and broods have proven difficult to find.
2008: A new effort was embarked upon in 2008 to determine the genetic diversity of southern Iowa's prairie chicken population. Trap lines were set out at the largest lek on the Kellerton Wildlife Area at the end of March and run through April $18^{\text {th }}$. Blood was collected from the 10 birds captured ( 7 males, 3 females) and sent for genetic analysis. Full results are still pending.

Booming males were counted on four leks this year all in Ringgold County. The biggest lek was once again at Kellerton Wildlife area where as many 14 males were initially observed booming though once the females appeared there were only 10 males. Current and prior lek locations are shown in figure 8.2.
2009: The newly established lek survey recorded 3 established lek sites in Ringgold County and one possible lek site in Adams County. The well established Kellerton lek had a high of 13 males and 4 females observed, while a smaller lek area to the north of Kellerton had a high of 4 males and 1 female seen during the survey (table 8.2). This smaller lek area was likely used by a total of 5 males and 2 females. One male was possibly heard booming at a lek area to the east of this smaller lek site. Another two male chickens were not seen, only heard at a possible lek area in Adams County.

In addition, a prairie chicken nest was located for the first time just southwest of the main Kellerton lek. Twelve eggs were counted and a later visit confirmed that 11 successfully hatched. A
further sighting of the brood recorded that two of the chicks had died and the remainder of the brood was not seen and their fate is unknown.
2010: The 2010 lek survey recorded 3 established lek sites in Ringgold County. The well established Kellerton lek had a high of only 8 males however a high of 7 was collected on another satellite lek site and an additional 4 were observed on the final lek site, north of Kellerton (table 8.2). Outside of the lek survey an additional 6 females were observed on one of the satellite lek sites. The average number of males observed per lek was the highest it has been in the previous 10 years at 6.33 . While this number should be somewhat encouraging it really seems to reflect the concentration of birds on fewer lek sites.

No prairie chicken nests or broods were located in the Kellerton area during 2010. However, two broods were flushed in two different fields at TNC's Dunn Ranch in northern Missouri. Other sightings in the Kellerton area include 2 observations of a winter flock containing 24-25 individual birds.
2011: Prairie Chickens were detected at 6 locations representing 3 lek sites. One of these areas, in Adams County, was previously unreported but despite additional visits with more intensive searching it was never confirmed as a lek site. It is presented here with the caveat that it is unconfirmed. A maximum of 6 males were detected at the lek on the Kellerton Wildlife Area. A maximum of 7 males were detected on the lek on private land northwest of the Kellerton Wildlife Area. The data for the lek in Adams County listed only "more than 1 " bird heard. No females were detected during the survey though up to 2 were seen at other times on the private lek.

Flushing brood surveys at the

Kellerton Wildlife Area on August 1 turned up 5 adult prairie chickens, 3 of which were female, but no broods. 2012: The 2012 lek survey covered a 25 mile radius around the two active lek/release sites and 47 sites were surveyed. All survey sites had been surveyed using the same methodology in 2011. Twenty-five sites were historically known lek sites and 22 were random survey points. Each site was visited around sunrise twice between April 1 and 25. Prairie chickens were detected on 4 different sites all on or within 1.5 miles of a currently active lek. A count of 14 birds was recorded on April $2^{\text {nd }}$ before the translocation began and 17 birds were detected on April $18^{\text {th }}$ including one bird seen on one new site. A survey of one active lek from a blind on April $17^{\text {th }}$ counted 8 males and 2 females present with one of the birds wearing a leg band from the translocation.

Two broods have also been detected through opportunistic observations. One was located on the Kelleron Wildlife Area and one on private ground about 2 miles Northwest of the Kellerton Lek. A total of 10 young were counted.
2013: The 2013 lek survey covered a 25 mile radius around the two active lek/release sites and 47 sites were surveyed. All survey sites had been surveyed using the same methodology since 2009. Twenty-five sites were historically known lek sites and 22 were random survey points. Each site was visited around sunrise twice between April 1 and 25. Prairie chickens were detected on 4 different sites all on or within 1.5 miles of a currently active lek. Post-release average counts of birds increased by an average of 1.23 birds from pre-release counts. The average maximum birds across the four active leks
was seven. The maximum number of birds seen on one morning during the booming season was 24 birds. Outside of the formal lek survey (and normal booming season) prairie chicken booming was heard on a historic lek to the north of Kellerton on June 6.

Ten of the hens that were translocated in 2013 were fitted with satellite GPS transmitters. Only one of the hens remains under surveillance as of September 2013 and she was located in Southwest Union County, IA. Up to that time she had traveled over 1000 miles in large loops through Southern IA and Northern Missouri. Seven of the ten hens were confirmed mortalities with the other two having an unknown fate.

Two broods have been opportunistically observed on Kellerton WA: one with six young on June 26 and one with four young on August $9^{\text {th }}$. No broods were observed on a pilot roadside brood survey conducted in mid-July. 2014: In 2014, two additional lek survey routes were added in Iowa based on the dispersal data from birds released in 2013. This expanded the area covered to include two additional counties and a total of 6 routes and 71 survey sites. Two routes were also surveyed across the border in Missouri. Each site was surveyed 6 times between March $21^{\text {st }}$ and May 8th. Prairie chickens were observed booming on two lek sites with a maximum of 21 birds counted in one survey.

Twelve of the translocated birds were fitted with GPS transmitters: 2 males and 10 females. As of August 26th, four out of the twelve birds are still being tracked (1 male and 3 hens) along with 1 hen from the 2013 release. Of the losses, seven are suspected mortalities and one slipped its transmitter. Two of the surviving hens successfully nested, one on the Kellerton Wildlife Area and the other
at Pawnee Prairie in Missouri. The third is suspected to have nested on Dunn Ranch based on behavior but a nest was never located.

A formal roadside brood survey conducted in July did not pick up any prairie chicken broods however a number of broods were identified opportunistically throughout the nesting season. Brood sightings began being reported on the $17^{\text {th }}$ of June and by July $15^{\text {th }}$ there had been 13 confirmed sightings of chicken broods, some with collared hens and others not. These 13 sightings probably translate into an estimate of 1113 separate broods, four in Missouri and 7-9 in Iowa. A total of 85 young were reported from these sightings, ranging from 3-13 with an average brood size of 7.27.

## DISCUSSION

Prairie chicken reintroduction efforts have resulted in a small population of prairie chickens in a concentrated area of southern Iowa and northern Missouri.

Pasture and hay are still primary land uses in this region which benefits the chickens. The Iowa Prairie Chicken Management Plan sets objectives for not only prairie chicken population numbers but also for enhancing this landscape to increase the amount of native grass and provide more habitat for chickens and other grassland dependent wildlife. The Iowa DNR and many outside partners (The Nature Conservancy, The Missouri Department of Conservation) are implementing many actions to make progress on those objectives.

## TRUMPETER SWAN RESTORATION

Prior to the settlement of Iowa, trumpeter swans nested throughout the state. However, wetland drainage and unregulated hunting of trumpeters soon brought their demise. Prior to 1998, the last pair wild nesting trumpeter swans in Iowa occurred in 1883 on the Twin Lakes Wildlife Area southwest of Belmond, Iowa in Hancock County. Some 115 years later, the first modern day hatch of three wild trumpeter swan cygnets occurred in 1998 in Dubuque County. In 2000, a second pair nested on a Winnebago County Conservation Board wetland (Russ Tract at Thorpe Park) 8 miles west of Forest City.

Trumpeter swans were first given nationwide protection in 1918 when the United States, Canada, and Mexico signed the International Migratory Bird Treaty. A nationwide survey in the early 1930's indicated that only 69 trumpeters existed in the continental United States with all those occurring in Red Rock Lakes National Wildlife Refuge in southwest Montana. The Red Rock Lakes became the nation's first National Wildlife Refuge because of the presence of these trumpeter swans.

## Trumpeter Swan Restoration Program

In 1993, the Iowa Department of Natural Resources developed a plan to restore trumpeter swans to the state. There were two primary objectives with this project.
The first objective of the plan was to restore a self-sustaining, migratory population of trumpeter swans to its former nesting range in Iowa. To accomplish this, a goal was set to establish 15 wild nesting pairs to the state by 2003. That goal was reached in 2004.

Due to the project's initial success, another goal was set to have 25 wild nesting pairs by 2006. That goal was reached in 2005. Birds used for restoration purposes in Iowa have been obtained from 26 different states, including zoos, private propagators, other state swan projects, and any other sources that might have available swans. A total of 121 sources have been used to date. Once in Iowa, flightless breeder pairs are established at appropriate sites, the young of which are released for free flight across the state. We have found it necessary to move young produced at these flightless pair sites. Otherwise they interfere with the following year's reproductive activity because the adult pair will continually harass the young in order to exclude them from their nesting territory.

The second objective was to use the swans to "Trumpet the Cause For Wetlands". There have been well over 350 swan releases done by DNR staff with the public and media invited to attend. At which times, the many positive values of wetlands have been discussed with the groups attending the swan releases. The swans have garnered a lot of attention and interest from the public and the media both. DNR staff has used these opportunities to explain to these groups the value of having healthy wetlands to support "charismatic mega-fauna" such as Trumpeter Swans.

Funding to help support the DNR with this restoration program has come from a wide variety of swan enthusiasts, conservation groups, and charities. Considerable soft match/in-kind contributions have been made and are conservatively estimated at over 1.5 million dollars. The Trumpeter Swan Program was also awarded a State

Wildlife Grant (SWG) in 2004. These funds have been used to help cover the costs of feed, vet care, nesting site preparations, equipment, and the purchase of swans.

## Marked Swans and Reported Observations

Through the summer of 2008 nearly all trumpeter swans released in Iowa were marked with plastic green or red neck collars and leg bands, along with U.S. Fish and Wildlife Service metal leg bands. The plastic neck collars and leg bands are marked with alpha letters C, F, $\mathrm{H}, \mathrm{J}, \mathrm{K}, \mathrm{P}, \mathrm{T}, \mathrm{M}$, and two numbers, 00 through 99. We have been disappointed that several of our marked swans have lost both plastic neck collars and legs bands and a few have lost the soft aluminum metal USFWS leg bands. Neck collar losses create problems analyzing both movements and mortality of Iowa Trumpeter Swans. In 2004, we began using stainless steel lock-on 9C FWS leg bands and we are not aware of any leg band losses since. During the last 4 years we have neck collared less than $5 \%$ of released swans

Iowa has the largest trumpeter swan observation database with over 4,100 observations of neck collared swans thru 2014. Iowa marked swans have been reported in 17 states, as far west as Colorado, east to Virginia and north into two Canadian provinces (Figure 3). After 10 years of migration observations, the largest concentrations of migrating Iowa swans are wintering in northeast and eastcentral Kansas and northwest and westcentral Missouri. One Iowa trumpeter swan wintered as far south as Oklahoma during the winter of 1998/1999. Also, one swan wintered near Heber Springs, Arkansas in 1999/2000. During the
winter of 2002-2003, 2 swans released at Hottes Lake near Spirit Lake, Iowa migrated to Lubbock, Texas. These are possibly the first known, or at least the first of very few interior swans to migrate to Texas since the 1880's. Migration movements "out of that norm" included 3 swans released at Union Slough NWR that migrated to and wintered in southeast Colorado near Ft Lyon. Two of these were observed at Monticello, Minnesota in the spring of 1997. The straight-line round trip mileage for these birds is over 1300 miles.
"Traditional" swan wintering sites are developing in Iowa. Sites include Bill Beemer's Pond, a private partner site near Webster City, a rock quarry at Atlantic in southwest Iowa, Bob \& Mary Boock's wetland near Wheatland in east central Iowa, Laurie Severe Pond near Nora Springs, and a rock quarry near Fertile, IA. A review of the last 15 years of swan sightings indicates most areas of the state are now seeing swans at sometime during the year. This is another indication that the restoration effort is moving forward.

## Trumpeter Swan Mortality Factors

Iowa currently has the dubious distinction of having one of the highest shooting mortality rates of any state in the Midwest. This high mortality rate is a concern because it could obviously negatively impact wild nesting swans in future years. We hope that with increased publicity, additional enforcement efforts, and public scrutiny, we will see the illegal shootings reduced. There have been 9 confirmed shootings of Iowa swans that occurred out-of-state, ( 1 in Wisconsin, 3 in Missouri, 5 in Texas). A \$17,000 fine was charged to four men in connection with the family group of 5 Iowa swans shot in Texas.

Two hundred ninety four known mortalities have occurred to date: 62 have died due to power line collisions, 55 poached by violators, 59 died due to lead poisoning, 11 due to apparent malnutrition, and 38 to diseases. Several other mortalities have likely occurred from unknown and unreported causes. Mortality rates are higher than anticipated and likely slow trumpeter swan restoration efforts. Shooting a trumpeter swan can result in a citation of $\$ 1500$, liquidated damages, court costs, and perhaps hunting license revocation.

## Current Status of the Trumpeter Swan Restoration Program

Trumpeter Swans are nearing sustainable numbers in north central and east central Iowa. As a result of the program's success, the Iowa DNR has significantly reduced their direct hands-on efforts of handling and transporting swans over the past three years. Instead, our time is now more focused on coordinating further swan restoration efforts with willing partners such as county conservation boards and private landowners with suitable nesting sites. Currently, there are thirty partnership breeding pair sites that are active.

Eighteen trumpeter swans were released in Iowa in 2014 (Table 1). A total of 1,150 trumpeters have been released to date. A total of 71 wild free flying Trumpeter swans have been captured, banded and released in Iowa since 1997 (Table 2). Also in 2014, 45 trumpeter swan nest attempts occurred in Iowa, slightly down from

46 nests in 2013 and 49 in 2012 (Figure 2).

Since 1998, 437 known trumpeter swan nests have occurred in Iowa (Table 3). Figure 1 shows the statewide distribution of these nesting attempts. The 2014 spring flash flooding resulted in the loss of at least two swan nests in northern Iowa and six nests in 2013. Higher cygnet mortality was also observed in 2013. In 2012 and 2013, dry weather and wetland conditions resulted in higher cygnet mortality and increased cases of lead poisoning. Many wetlands went completely dry in August and cygnets were forced to walk overland in search food and water. All wildlife populations are cyclic so we know that nest attempts will show ups and downs over the duration of the trumpeter restoration efforts. Each year there could also be 4 or 5 other nest attempts that we do not know about as we have had at least a few families of swans show up in the state prior to normal migration dates. Also of note, we have several pairs of Iowa swans nesting in Southern Minnesota and Wisconsin.

A total of 458 trumpeters were tallied during the mid-winter waterfowl survey in January 2014, down from 747 tallied in January 2013 (Table 4). If swans can find open water and food, many of them will remain throughout the winter. These "winter" sites have provided many people the opportunity to view these "charismatic-mega fauna."
The DNR and many Iowans are very excited about the future of trumpeter swans in the state and hope their numbers remain strong.

## OSPREY RESTORATION

Osprey, Pandion haleatus, commonly called the fish hawk or fish eagle, is neither a true hawk nor eagle. Ospreys are cosmopolitan and occur worldwide with the exception of Antarctica. The species is of ancient lineage and presently is classified near the kite family. There are four subspecies presently recognized, two occurring in North America, P.H. carolinenses and P.H. ridgwayi. Ridgwayi is found in the Bahamas and Caribbean, while carolinensis is the Midwestern species. Carolinensis is migratory in its northern range and resides in south Florida and possibly part of the Gulf coast and northwest Mexico.

Ospreys were never confirmed to historically nest in Iowa, but were probably here given the abundance of lakes and wetlands that dotted the prairie. Ospreys are very unwary birds and territorially appear weak. Pairs will nest colonially. Nests may be upon structure, manmade or natural, that provides a platform, but Ospreys have been known to nest on the ground. Nests are generally at least one-foot deep and four to five feet wide, are made of sticks and lined with grass. Highest productivity is attained on power poles and nesting platforms.

Ospreys were heavily affected by the biocide crash of the 1950s. Populations were severely reduced throughout the range but hardest hit in the Great Lakes and Atlantic coast. A strong fidelity to ancestral breeding areas slowed range expansion into vacant and newly created habitat since the DDT era.

With construction of lakes by Department of Natural Resources and reservoirs by U.S. Army Corps of Engineers, potential osprey habitat exists
that was previously not available. There are numerous osprey summer sightings in Iowa, but apparently these young, non-breeding ospreys return to northern areas for mating and nesting. Despite this population growth, ospreys have demonstrated little breeding range expansion. Minnesota and Wisconsin DNR officials suggest that ospreys, in our lifetime, do not readily pioneer new breeding ranges. Instead they experience suppressed reproduction as density of breeders increase. To address this issue, young ospreys from Wisconsin and Minnesota are being relocated to areas with suitable habitat in southern Minnesota, Iowa, Kansas, Missouri and Ohio.

The Iowa Department of Natural
Resources has assisted conservation partners with technical assistance, encouragement, and fish to successfully release ospreys in Iowa. The Macbride Raptor Project located near Coralville Reservoir has spearheaded this work. Beginning in 1997, four or five young ospreys have been released annually at their facility until 2002. Personnel at the Hartman Reserve Nature Center and volunteers in Cedar Falls initiated a release at their facility in 1998. Staff of Boone County Conservation Board and Polk County Conservation Board with volunteers coordinated a release at Saylorville Reservoir in 2000. Boone Co. staff and volunteers began releases at Don Williams Lake in 2003. Wickiup Hill in Linn Co. and Clear Lake were added in 2004. The U.S. Army Corps of Engineers has provided distinguished service for releases at Coralville and Saylorville Reservoir respectively. Assisted by literally hundreds of volunteers, these conservation organizations have devoted their efforts
to bring ospreys to Iowa as a nesting species. A four-year minimum commitment of releasing ospreys is required at each site. Project fundraising is the responsibility of the conservation organizations doing the releases. Ospreys cost about $\$ 500$ per bird.

In Iowa, ospreys have two bands, a silver U.S. Fish and Wildlife Service band and a numbered, lavender band on separate legs.

Forty-eight ospreys have been released at the three sites since 1997.

Beginning in 2000 Osprey released in SW Minnesota by Minnesota DNR, built a nest atop a microwave tower near Cayler Prairie in NW Iowa. In late winter Great-horned Owls were seen at the nest and tending young, however by April the Ospreys were once again nesting at the site. Incubation appeared to be progressing, but ultimately the nesting attempt failed. It was believed extremely violent storms were a factor in the demise of the nesting attempt. A second pair was also observed nest building in the Spirit Lake area. At Coralville reservoir a 1998 released Osprey was nest building with two other unidentified adult Osprey. The adults were seen feeding the yearclass of 2001.

## 2014

In 2014 there were 21 Osprey nest attempts with 15 successful nests produced 30 young. This year six Ospreys were brought to Iowa from Minnesota and released at two sites.

At Swan Lake in Carroll CCB staff with Kay Neumann and Saving Our Avian Resources placed three Ospreys. One was outfitted with a transmitter to provide information about migration and mortality.

At Clear Lake Ron Andrews and local staff at the Baptist Camp placed three Ospreys.

At Annett Nature Center, Warren CCB staff reported pair nest-building but did not proceed to nesting.

There were five wild nesting pairs at Lake Macbride. The site off Scales Bend Road produced two young. Staff was unable to read adult bands, if any. The site at Sugar Bottom had one young. The female was unbanded and the male was unconfirmed. Another site at Lake Macbride came down and no young were reported. One of adults had a purple band.

There is a new nest near Solon High School parking lot. Another new nest has been established at Sand Lake, in Johnson County, but no report of young.

At Jester Park in Polk County, no young were produced from the pair at campground \#6.

A pair at Walnut Woods built a sizable nest in 2009 and produced three young.

A nest one mile east of Big Creek State Park was active. Two young were noted in August.

A nest on a cell phone tower SW of Jordan Creek Mall in eastern Dallas Co. fledged two. One and one half mile east of this tower at Jordan Creek Mall a pair of Ospreys carried sticks to a construction crane. There is interest to place a pole with a platform when crane leaves in September.

A nest at Camp Dodge near Saylorville Reservoir had two young. At Don Williams lake in Boone County three pairs were reported in the area. Canada geese were occupying a previous nest site. A pair attempted to nest near the dam, but was unsuccessful.

In Cedar Falls, a pair returned to successfully nest upon an IWireless cell phone tower. One adult is band \#A/T from White Rock 2006. The pair produced two young. A pair at Evansdale produced two young. At Duane Arnold Plant a pair from Wickiup Hill in Linn Co. produced two young, and a second Linn Co. nest south of Palo fledged two young. A possible third nesting pair is in area.

At Spirit Lake, a pair nested near the Nature Center release site. Two young fledged. A nest at Lower Gar fledged two young.

There is a nesting pair just south of Sioux City near Sergeant Bluff in Woodbury Co. The Cell Tower pair produced two young according to Jerry Von Ehwegen. Also according to Rich Pope, there was pair at their farmsite south of Sloan in Monona Co. However a wind storm destroyed the young in the nest.

There is a new nest on a cell tower along US 20 at Independence in Buchanan Co. At least one young was produced.

In summary for 2014, 21 nesting pairs had 15 successful nest attempts with 30 young produced. Since 1997, 297 Ospreys have been released at twelve sites in Iowa. Since 2003, 164
wild Ospreys have been produced at 95 successful nests.

Ospreys in lowa 2014

## SANDHILL CRANES IN IOWA

Prior to European settlement of Iowa, Sandhill Cranes probably were a common nesting species and abundant migrants. As early as 1820, Edwin James saw large flocks of cranes migrating north along the Missouri River in Harrison County. Even in the 1890's, it was not uncommon to see flocks of hundreds or even thousands of cranes in Winnebago and Hancock Counties in spring. Although there are few specific records, Sandhill Cranes probably were fairly common nesters in north-central and northwest Iowa. With settlement, the combination of unregulated hunting and loss of nesting habitat led to a rapid disappearance of nesting cranes from Iowa. The last Sandhill Crane nesting of that era was at the headwaters of the Iowa River near Hayfield in Hancock County in May 1894. As was common in those days, the eggs were taken for an egg collection.

Cranes nest in shallow wetlands with dense vegetation. They create a nest mound by pulling up marsh plants and laying one to three eggs that hatch in late spring. About three months after hatching the young begin to fly, but the brownish-colored young remain with their parents throughout their first winter. Cranes eat waste grain, seeds, berries, roots, tubers, snakes, frogs, crayfish, worms and insects.

By the early 1900s, even migrating Sandhill Cranes were rare in Iowa. For the next 60 years, there are very few reports of cranes in Iowa. Throughout the Midwest, problems similar to Iowa's caused Sandhill Crane populations to dwindle. Just a few dozen pairs remained in Wisconsin, Minnesota and Michigan through the

1940s. During the 1970 s and 1980s, however, nesting populations increased in the northern states, and a few migrating sandhills were seen in Iowa.

The number of Sandhill Cranes reported in Iowa increased greatly in the late 1970s and 1980s (Dinsmore 1989), culminating in their return as a nesting species. Nesting birds derive from populations in Wisconsin, which increased greatly in the 1970s and 1980s (Robbins 1992) and eventually spilled over into Iowa. These birds winter in Florida and Georgia. The huge flocks that gather in central Nebraska nest in the Arctic. Those flocks are probably the source of most cranes seen in western Iowa (Kent and Dinsmore 1996).

In 1992, after a 98-year absence, Sandhill Cranes successfully nested in Iowa at Otter Creek Wildlife Management Area in Tama County. Two colts were produced. In 1993, cranes also attempted to nest at a second area at Green Island along the Mississippi River in Jackson County, however due to annual flooding, young were not produced at that site until 1997. In the mean time cranes at Sweet Marsh became established and successfully nested, beginning in 1994. The Sweet Marsh flock has grown to include four other sites in Bremer Co.
$\underline{2002}$
In 2002, Sandhill Cranes were observed in four new sites. Reports were received of cranes sited in Clinton and Chickasaw County. Allamakee County picked up another site where young were produced and in western Iowa, young were produced in

Woodbury County. Cranes have been included in bird counts in at least 14 counties during the year.
$\underline{2003}$
In 2003 unison calling between adults increased to 27 pairs around the state. There were 95 known sightings and fifteen documented young around the state. Dr. Jim Dinsmore provided a sightings file that included a number of counties where cranes were seen in recent years.

In Boone County a nesting pair had wintered at a farmstead south of Madrid. The pair performed nesting courtship displays and created a nest in the farmyard. Two eggs were laid in the spring. In April the nest and eggs were destroyed. Raccoons or dogs were suspected. In June a Sandhill Crane carcass was discovered in the vicinity of the nest near powerlines. The fate of this unconventional pair is unknown.
$\underline{2004}$
In 2004 cold, wet spring conditions hampered Sandhill Crane nesting in Iowa. Twenty-seven pairs of cranes were reported but only seven young hatched. However, most sites had summering cranes and additional pairs were reported near Belle Plaine, Chickasaw Co., and Olin in Jones Co. Jones County became fifteenth county documenting crane nesting.
$\underline{2005}$
Exciting news in 2005 includes successful nesting of cranes in Winnebago County. CCB Director, Robert Schwartz, reported a colt at Hogsback Wildlife Area. Also DNR Biologist, Bill Ohde, reported a new pair at Wiese Slough in Muscatine County that produced one young. Ric Zarwell,
in Allamakee Co., reported four pairs with four young. Across the state 20 pairs were reported with nine pairs that successfully reproduced 13 young. Including Winnebago and Muscatine Counties, Sandhill Cranes have now been reproduced in 17 counties.

## $\underline{2006}$

In 2006 a favorable nesting season has maintained our Sandhill Cranes nesting population at 17 counties. Two notable crane sightings occurred when Whooping Cranes were reported in Iowa. During spring migration five whoopers stayed over in Winnebago Co. A second flock of eight whoopers were discovered in northeastern Iowa. By early June all had left Iowa and returned to their home at Necedah National Wildlife Refuge in Wisconsin. In September three of the five Whoopers returned to Winnebago Co. As of 2005 there were only 336 whoopers in the wild and 135 in captivity.
$\underline{2007}$
In 2007 Sandhill Crane sightings were included in three new counties: Palo Alto, Greene, and Madison Counties. Also Crane reproduction was noted at Chichaqua Bottoms in Polk Co. bringing our total to 18 counties with cranes successfully nesting.

Also, during this past summer there were record numbers of Whooping Crane chicks hatched at Wood Buffalo National Park in northern Canada. An aerial survey of the breeding grounds found 65 nests and 84 new chicks. The new Whooping Crane chicks include 28 sets of twins. This year's offspring come after last year's encouraging numbers of 76 new chicks - including 24 sets of twins.

## 2008

Record flood levels in 2008 suppressed nesting crane reproduction around the state, but good numbers have been frequenting our marshes during autumn migration of 2007. Otter Creek Marsh in Tama Co. and Sweet's Marsh in Bremer Co. reported flocks of 25 and 27 birds last autumn. This nesting season Sweet Marsh reported 15 birds with five unison calling pairs. Otter Creek had 18 cranes with two pairs producing one young each. Allamakee Co. distinguished itself with 22 cranes sighted during spring survey and four unison calling pairs. Although there has been limited growth of crane population and subsequent reports around the state, cranes are increasingly appreciated by birding community and conservation groups dedicated to providing marshland habitat around the state.

2009
In 2009 the weather during the crane survey in April was quite favorable. Twenty five pairs have been reported with two counties, Muscatine and Woodbury, including crane sightings after a few years of not recording any sightings. With suitable nesting habitat being emphasized in every county, it is hopeful Sandhill Cranes will maintain their incremental growth in reproduction. A pair near Comanche, Iowa raised young at a five acre wetland near Hwy 30.

## $\underline{2010}$

Wetland conditions during the Crane Survey in April, 2010 were quite favorable for successful nesting as record snowfall provided the melt water to fill wetland basins. With a wetter than normal summer we should see moderate population changes, if summer

2010 flooding is similar to the 2008 flooding around Iowa. At this time, good reproduction has occurred at enough sites to maintain our optimism that Iowa's Sandhill Crane population is continuing to increase. Autumn flights of cranes around Pool 9 of the Mississippi River, Otter Creek Marsh and Sweet's Marsh are providing outdoor enthusiasts opportunities to see Cranes on Iowa wetlands. About 110 cranes were observed during this spring's survey. Nesting success was confirmed for 11 pairs, resulting in a 2010 production of 14 colts.
$\underline{2011}$
Wetland conditions during April, 2011 were good, but the weather on survey day was challenging with 35 degrees and wind gusts to 40 mph . With a wetter than normal spring we will see moderate population ebbs and flows. However, good reproduction has occurred in enough sites to maintain our optimism that our Sandhill Crane population continues to increase. Most exciting area that cranes have discovered is Mitchell Co. along Cedar River in north central Iowa. Cranes have reproduced in 22 counties since 1992. Autumn concentrations of cranes around pool nine on the NE Iowa portion of the Mississippi River, Otter Creek Marsh and Sweet's Marsh are providing outdoor enthusiasts spectacular flights and social interactions of Cranes adapting to Iowa's wetland complexes. Each autumn Iowa's Sandhill Cranes are establishing concentration or staging areas at Sweet Marsh where 35 have been reported, Green Island Bottoms along Mississippi River in Jackson co. with 35 more, and Otter Creek Marsh in Tama County where 54 were reported in October, 2010. This is
an exciting development that has grown incrementally since the first successful nesting at Otter Creek Marsh in 1992.
$\underline{2012}$
Wetland conditions during April, 2012 were exceptional throughout the nesting season. Summer drought conditions created wildlife hardships but cranes fared as well or better than the majority of species surveyed. Good reproduction has occurred in enough sites to maintain our optimism that our Sandhill Crane population continues to increase. Cranes have reproduced in 21 counties since 1992. Autumn concentrations of cranes around pool nine on the NE Iowa portion of the Mississippi River, Otter Creek Marsh and Sweet's Marsh are providing outdoor enthusiasts spectacular flights and social interactions of Cranes adapting to Iowa's wetland complexes. Each autumn Iowa's Sandhill Cranes are establishing concentration or staging areas at Sweet Marsh where 42 have been reported a record high, Green Island Bottoms along Mississippi River in Jackson co. with 35 more, and Otter Creek Marsh in Tama County where 107were reported in October, 2011. This is an exciting development that has grown incrementally since the first successful nesting at Otter Creek Marsh in 1992.
$\underline{2013}$
Weather conditions during April and May were wetter and colder than normal in 2013. The interior Crane nesting areas in Tama and Bremer counties saw precipitation that was 10 inches above normal during May, and May snowfall totals of 4 to 8 inches. Following the severe flooding of May
the precipitation ceased and a drought persisted throughout the summer.

Crane reproduction was reported at enough sites to maintain our optimism that our Sandhill Crane population continues to increase. Cranes have reproduced in 21 counties since 1992. Autumn concentrations of cranes around pool nine on the NE Iowa portion of the Mississippi River, Otter Creek Marsh and Sweet's Marsh are providing outdoor enthusiasts spectacular flights and social interactions of Cranes adapting to Iowa's wetland complexes. Each autumn Iowa's Sandhill Cranes are establishing concentration or staging areas at Sweet Marsh where 42 have been reported a record high, Green Island Bottoms along Mississippi River in Jackson co. with 35 more, and Otter Creek Marsh in Tama County where 107were reported in October, 2011. This is an exciting development that has grown incrementally since the first successful nesting at Otter Creek Marsh in 1992.

In November 2012 there were 98 cranes reported statewide with 35 at Sweet Marsh, 40 at Otter Creek and 18 at Green Island. Crane calling was noted at Kirchner Prairie marsh in Clay Co. in mid Nov.

In October 2013 there were 78 reported with the majority, 59, at Otter Creek Marsh. Temperate autumn conditions have resulted in a slower than normal migration but cold fronts in the forecast will create change. Anticipation is high that Iowa's growing crane population will continue upward trends.

## $\underline{2014}$

Wetland conditions during April, 2014 were exceptional throughout the nesting season. Good reproduction has occurred in enough sites to maintain our
optimism that our Sandhill Crane population continues to increase. This year four new counties documented reproduction: Wright, Howard, Delaware and Johnson Counties. Cranes have reproduced in 26 counties since 1992. Autumn concentrations of cranes around pool nine on the NE Iowa portion of the Mississippi River, Otter Creek Marsh and Sweet's Marsh are providing outdoor enthusiasts spectacular flights and social interactions of Cranes adapting to Iowa's wetland complexes. Each autumn Iowa's Sandhill Cranes are establishing concentration or staging areas at Sweet Marsh where 42 have been reported a record high, Green Island Bottoms along Mississippi River in Jackson co. with 35 more, and Otter Creek Marsh in Tama County where 117were reported in October, 2013. This is an exciting development that has grown incrementally since the first successful nesting at Otter Creek Marsh in 1992.

In November 2013 there were 95 cranes reported statewide with 35 at Sweet Marsh, 40 at Otter Creek and 18 at Green Island.
Our documentation of crane nesting in Iowa will receive a boost in 2015. Our Volunteer Wildlife Monitoring Program will assist crane enthusiasts in focusing on sites that have known crane activity. It is not always conducive to see young or colts at many sites as the marsh seems to swallow their presence. 2014 was a good year for Sandhill Cranes in Iowa.

Sandhill Cranes in lowa, 2014

## BALD EAGLE RESTORATION

## HISTORICAL REVIEW

When Euro-Americans first arrived in Iowa, it is likely that bald eagles nested throughout the state, particularly in the woodlands along rivers, streams, and fish infested lakes. As forests were cut and the woodland habitat occupied by eagles was altered, eagle numbers declined. Direct persecution (mostly shooting) and changes in eagle habitat, particularly nesting habitat, appear to have eliminated the bald eagle as an Iowa nester by the early 1900s. Early records for the bald eagle in Iowa do not give us a good idea of how many nests there once were for this species, but we do know that eagles were "formerly common in Iowa and frequently nested in favorable localities" (Anderson 1907). It appears that the last nest documented near the turn of the last century was in Jasper County in 1905, where two young eaglets were taken from a nest near Kellogg (Anderson 1907).

The passage of the Federal Bald Eagle Protection Act of 1940 was the first real effort to protect eagles, especially from shooting. The use of organochlorine pesticides (such as DDT) after World War II also severely devastated eagle populations (Broley 1958, Carson 1962). It was only after the banning of organochlorine pesticide use in this country in 1972 and the listing of the bald eagle for protection on the Endangered Species Act in 1978 that this species began to recover. The bald eagle was considered an extirpated species on Iowa's first threatened and endangered species list in 1977 (Roosa 1977), and it was not again expected to be seen nesting in Iowa.

## MORE RECENT IOWA NESTING RECORDS

As improbable as it seemed, the bald eagle did nest in Iowa again. The first nest noted in over 70 years was located near New Albin on the Mississippi River floodplain in 1977 (Roosa and Stravers 1989). Two young were produced that first year, but it was not until 1980 that another eaglet was produced from that nesting territory. In 1984, Dinsmore et al. (1984) considered the bald eagle a rare summer resident. It was in 1985 that a second Iowa eagle nest appeared, just three miles downstream from the first. That nest produced three young. During 1986, a third nesting territory appeared in Allamakee County on the Mississippi River, and a fourth occurred in Jackson County. The first documented nest away from the Mississippi River was found in 1987 along the Skunk River near Coppock in Jefferson County (Figure 15.1). The following year there were eight active nests reported. Two more new nests were discovered away from the Mississippi River, one in Allamakee County and one in Fremont County near Forney's Lake. A new nest was also found in Clayton County along the Mississippi River, and a nest in a huge cottonwood tree was reported by towboat captain, Pat Flippo, for Des Moines County near the mouth of the Skunk River.

As part of the USF\&WS regional plan for bald eagle recovery, in 1981 Iowa established a goal of 10 active Bald Eagle nests by the year 2000 (Grier 1988). This goal was surpassed in 1991 when the number of active nests jumped to 13 . Nest numbers climbed to 21 in 1992, to 43 in 1995, and to 84 in 1998 - the last year in which most Iowa nests were monitored closely. At that time, bald eagles had nested in 42 different counties. The number of eagle pairs continued to grow, and by 2004, eagles had been reported nesting in 66 counties. Adams, Henry, Poweshiek, and Ringgold counties were the 2004 additions. During 2005, five more counties (Polk, Marshall, Story, Montgomery, and Kossuth) reported eagle nesting for the first time, bringing Iowa's eagle nesting county total to 71. Similarly, during 2006, six additional counties (Dickinson, Franklin, Boone, O'Brien, Wapello, and Page) reported eagle nesting, and five new counties (Hancock, Harrison, Cedar, Greene, and Lee) reported eagle nests in 2007. In 2008, eagle nesting was confirmed in Davis and Pottawattamie counties, and in 2009, Cerro Gordo and Emmet counties reported their first eagle nesting. Bald eagle nests were reported for Clarke and Winnebago counties in 2010 and for Grundy, Wright, and Pocohontas counties in 2011. During 2012, an active nest was confirmed for Audubon County, and during 2013 confirmed nesting was documented in Madison, Crawford, and Shelby counties. There are now ninety-five counties with documented eagle nesting (Figure 15.1), and approximately 614 bald eagle territories have been reported to the Iowa DNR since 1977.

In 2012, reports were received for 307 territories, with 48 reported for the first time. Roughly $72 \%$ (222) of the territories were reported active in 2012, and $21 \%$ (65) were reported inactive. The remaining 20 territories were reported with unknown activity. Forty-seven percent $(\mathrm{n}=104)$ of the active territories reported in 2012 included data on the outcome of the nesting season. Fifteen (14\%) of the 104 nests ended up failing, and 89 ( $86 \%$ ) were successful in producing young. For the 98 territories for which we have a good count of fledglings, a total of 151 young were produced, which averages to 1.54 young produced per nest. If we extrapolate, assuming $86 \%$ of all nests reported as active are successful; this produces an estimate of 294 young fledged from Iowa nests in 2012.

The opportunistically reported data is important because it is the primary source of new nest reports and does provide a valuable yearly snapshot. However, the full dataset, including the opportunistic reports, may not be representative of the nesting population as a whole and is misleading when examining trends across years. The sentinel territory monitoring put into place in 2010 compensates for some of these full dataset weaknesses.

For 2012, the sample size of sentinel territories was 136. Monitors were found for 95 of these territories and data was received on $77(81 \%)$ of these territories. This represents $23 \%$ of the known active territories (objective is to get data on $25 \%$ ). Within the 77 territories, 61 were active ( $79 \%$ ), 13 were inactive ( $17 \%$ ), and 3 could not be found or had unknown activity. The outcome of the 61 active nests broke down as follows: 45 successful, 3 failed and 13 unknown. Seventy-one young were produced by the active nests: 3 nests fledged no young, 8 nests fledged 1 young, 27 nests fledged 2 young, and 3 nests fledged 3 young. The estimated number of young produced per nest was 1.48.

During 2013, reports were received for 347 territories, and 59 territories were reported on for the first time. Approximately $69 \%(241)$ of the territories were reported active in 2013, and $18 \%$ (63) were reported inactive. There were 43 territories for which the activity was unknown. Nesting outcome data was collected on $45 \%$ (109) of the territories reported as active. Eighty-six (79\%) of those active nests successfully produced young, and it appears that 23 ( $21 \%$ ) produced no young. A total of 148 young were produced, producing an average of 1.36 young per active nest. Extrapolating from the data collected, an assumption is made that $79 \%$ of all nests reported active will be successful. In other words 190 active nests would produce an estimated 258 young eagles fledged. Projected eagle nest numbers (based on number of new nests reported each year and average nest increase rate since 1998 is shown in Figure 15.2 for 1999-2013.

## Sentinel Territory Monitoring Data

Also during 2013, the sample size of sentinel territories was 130 . Monitors were found for 98 of these territories and data was received on $80(82 \%)$ of these territories. This represents $34 \%$ of the known active (non-Mississippi River) territories (objective is to get data on $25 \%$ ). Within the 80 territories, 65 were active ( $82 \%$ ), 12 were inactive ( $15 \%$ ), and 3 could not be found or had unknown activity. The outcome of the 61 active nests broke down as follows: 40 successful, 6 failed and 19 unknown. Seventy-two young were produced in the active nests: 6 nests fledged no young, 10 nests fledged 1 young, 28 nests fledged 2 young, and 2 nests fledged 3 young. The estimated number of young produced per nest was 1.57 . In addition, for the 38 nests monitored most closely, it appeared that $95 \%$ of chicks observed in nests reached fledging age.

While there were record numbers of Bald Eagle territories reported in 2013, it appears the unstable weather (especially the wet spring followed by drought) adversely affected nesting activity and production. Only $69 \%$ of Iowa nests appeared to be active, while the 16 -year average is $75 \%$.

Midwinter Bald Eagle Survey: Beginning in 1983, ICC staff cooperated on a national Midwinter Bald Eagle Survey to assess the health of the greater bald eagle population. In cooperation with the National survey coordinator, USGS Raptor Research and Technical Assistance Center in Boise, Idaho, IA DNR Wildlife Diversity Staff continue to coordinate this survey today. Data from this survey indicate a dramatic increase in Iowa winter bald eagle numbers since 1993 (Figure 15.3). An especially high count $(2,493)$ during the winter of 2001 was related to harsh weather conditions and the subsequent concentration of eagles in count areas of the Mississippi River. Very mild winter conditions during surveys conducted in 2002 and 2003 were reflected in lower count numbers, which were still higher than any year prior to 2001. Cold winter weather again forced eagles south into Iowa during the next winter, and the 2004 survey results documented 4,432 bald eagles along Iowa's rivers; particularly along the Mississippi River. Milder weather conditions during the January, 2005 survey resulted in eagles being more spread out, and a reduced total (from 2004 count) of 3,164 bald eagles was
tallied. The mild winter weather trend continued for the January, 2006 survey, and only 2,592 bald eagles were counted within the state. Similar mild conditions occurred for the 2007 count, with 2,431 bald eagles tallied during January. In 2008, cold weather returned, and Iowa's January count found 3,913 bald eagles within Iowa borders. During the January 2009 survey, 2,534 eagles were counted, and 2,566 bald eagles were tallied during the January 2010 survey. A total of 3,674 Bald Eagles were counted in 2011, which is the highest number since $2008(3,913)$.

The number of eagles counted in the 2012 Midwinter Survey was roughly the same as numbers from 2011. In 2012, a total of 3,232 Bald Eagles were counted; that total remained higher than the previous 10 year average of 2991. Iowa wintering eagle numbers were down again in 2013, when 2,759 bald eagles were tallied. In spite of decreased numbers of eagles counted during 2009, 2010, and 2013 surveys (perhaps partly due to variable weather conditions during surveys and large fluctuations in food resource availability), the overall population trend is upward. It is likely that the severe drought conditions, prevalent in late 2012, did affect the count, since low water conditions existed in most waterways in January 2013. As usual, the majority of eagles counted were associated with the Mississippi and Des Moines rivers.

There was a total of 4957 Bald Eagles counted during January 2014 - the highest number of eagles counted in the history of the survey (Fig. 15.3). This count was significantly above the 10 year survey average of 2991 eagles. The average number of birds counted per route was 97 ( 2.8 eagles per mile surveyed). Surveying 1667 miles of habitat, 51 routes were completed in 46 counties. The extremely cold winter caused a high percentage of ice cover on rivers, and subsequently about $85 \%$ of all eagles were counted along the Mississippi River, especially below the locks \& dams where water was open.

## DISCUSSION

Both nesting and winter survey data were used for evaluating the delisting of bald eagles in the United States. Such information was used to upgrade the bald eagle national status from Endangered to Threatened in 1995, and in August 2007, the bald eagle was removed from the Federal Endangered/Threatened Species list. Iowa upgraded bald eagle from Endangered to Special Concern status in 2009.

Undoubtedly there are several reasons why nesting Bald Eagles have staged a comeback in Iowa. One reason for the recovery may be related to this species' ability to pioneer into suitable nesting habitat. This was not only true of Iowa's first nest in seven decades, which appeared in Allamakee County, but it also became obvious in 1987 when a pair of eagles nested in Jefferson County along the Skunk River. It was further evidenced in 1988 when an eagle pair nested in extreme southwestern Iowa in Fremont County near the Missouri River. Another key element helping eagle recovery appears to be Iowa's close proximity to one of the more stable nesting populations of bald eagles in the continental United States. Three states to the north, including Minnesota, Wisconsin, and Michigan, presently have a combined total of approximately one-third of all nesting eagles in the lower 48 states. There is little doubt that Iowa's eagle population has
benefitted from its neighbor states to the north. In 1998, when eagle nests occurred in 42 counties, over half of all Iowa's eagle nests could be found in four counties in the northeastern corner of the state. That phenomenon appears to hold true today, even though there are now about seven times the number of nesting eagles in the state.

An unanticipated factor that has helped bald eagle numbers recover is the species' adaptability. It appears that eagles nesting in the Mississippi River floodplain may be somewhat tolerant of boat traffic (McKay et al. 1995). Other instances indicate that some eagles are more tolerant of disturbance than others. There are now numerous nests located within several hundred yards of buildings, roads, and farm fields. One nest along the Upper Iowa River in Howard County was only about 100 yards from the bedroom window of very interested eagle nest watchers. The nest was located on the opposite side of the river, which probably minimized the impact of human activity. Grier (1988) explained that eagles' ability to tolerate human activity and nest close to buildings has "broadened their amount of available habitat and living space."

## THE FUTURE

Although the outlook for Iowa's eagle population is favorable, there are still factors that affect eagle numbers. Unmanaged logging can pose a threat to eagles, and the removal of large, mature cottonwoods along Iowa streams limit where eagles can nest and find foraging perches. Logging in the vicinity of eagle nests also can affect the nesting outcome, especially if done during the nesting season. Even though there are strict federal laws protecting eagle roost and nest sites against disturbance during their occupancy, cutting of roost trees of bald eagles during the time of year that eagles are not using them is not prohibited.

Lead poisoning is still a concern, as a number of eagles are found in Iowa each year, either dead or suffering from this problem. Five out of eight bald eagles found sick in Iowa and brought to wildlife rehabilitators between November 1998 and January 1999 suffered from lead poisoning. Iowa's Wildlife Rehabilitators report that of the bald eagles received by rehabilitators and tested for presence of lead since January 2004, approximately $50 \%$ show elevated levels of lead. Since 1996, an average of $25 \%$ of the bald eagles admitted each year to The Raptor Center at the University of Minnesota have toxic levels of lead in their blood. Where the majority of this lead is coming from is yet to be determined. Iowa State University graduate student, Billy Reiter-Marolf completed his study that involved collecting eagle droppings at eagle nest and roost sites to determine if lead is present in breeding and wintering eagles. His study results indicated that lead did not appear to be affecting the larger eagle population, and Iowa's eagle nest monitoring efforts indicate its population is still holding its own.

Overall, bald eagle numbers continue to recover. In 1963, an Audubon Society survey found only 417 remaining bald eagle nests in the continental United States. It was a species headed for extinction. In 2006, the U.S.F\&WS estimated about 9,500 active nests
in the lower 48 states. Iowa, which had no nests for over 70 years, in 2013 had approximately 300 active nests. The enforcement of protective laws and a change in the public's attitude toward eagles have helped bring back this species.

Bald Eagle Appreciation Days: Iowa DNR staff have been involved with promoting the appreciation of bald eagles since helping establish the first event in Keokuk in 1985. There are presently at least 13 Bald Eagle Appreciation Days held in Iowa each winter to celebrate the existence of eagles, and between 35,000 and 45,000 people gather at these events annually. With the continuation of public support for bald eagle recovery, this bird's population should continue to increase.

## ACKNOWLEDGMENTS

Stephanie Shepherd, a DNR Wildlife Diversity Program Biologist, coordinates the effort to monitor both Iowa's nesting and wintering Bald Eagles and provided the data for this report. Our thanks to the many Iowans who continue to monitor our eagle nests, continue to help with winter eagle surveys, and provide information that better helps the different agencies protect and manage for this species.

# MOUNTAIN LION/COUGAR STATUS IN IOWA <br> 1995-2013 

The mountain lion/cougar (or puma, panther, and various other names) is the largest of the three wildcats historically documented in Iowa. The lynx and the bobcat are the other two. The mountain lion/cougar probably occurred throughout most of the state originally, but nowhere in great numbers. The lynx has been extirpated and the bobcat is established in Iowa again after nearly being extirpated. The last historical record of a mountain lion/cougar in Iowa was one that was shot in 1867 in Appanoose County near the town of Cincinnati, Iowa.

Since the mid-1990's, the DNR has received several reports of large "cat" like sightings which led some to believe that a few "free ranging" mountain lions/cougars may again be occurring in some portions the state. These "free ranging" mountain lions/cougars could be either escapees, or released animals, privately owned, (grandfathered in before July 1, 2007 legislation to curtail the ownership of certain "dangerous wild animals") or they are fully wild animals dispersing from western and southwestern states. Southeast South Dakota, eastern Nebraska, northeast Kansas, Missouri, as well as Minnesota, Wisconsin, and Illinois, have reported increased mountain lion/cougar sightings during the past 10 years.

## Confirmed Mountain Lions in Iowa

Figure 1 is a map showing mountain lion sightings reported to the DNR that were confirmed or highly probable confirmations (1995-2013). Tracks and/or sightings reported to us throughout the year are documented as confirmed or unconfirmed after
investigating the evidence. This past year (2013), the Iowa DNR confirmed two mountain lion reports (Table 1). One mountain lion was captured on game cameras multiple times in Warren County, while the second mountain lion was shot in early December in Sioux County. Table 2 shows the number of confirmed mountain lions in Iowa by year. The following methods have been used to confirm the presence of mountain lions in Iowa to date: roadkills, shot and killed, verified camera pictures, and sightings (Table 3).

It is important to note that an average of 2 to 4 sightings per week is reported to us in the Clear Lake office from locations all over the state. This does not count all of the reports other DNR staff receive in their regions throughout the state as well. Over 2,000 mountain lion sightings have been reported since 2010. However, strong evidence in the form of legitimate tracks, photos, video or other evidence is necessary before we can officially place them on our map as "confirmed".

It is very likely that we have the occasional mountain lion wandering through or staying in our state for a period of time, however we have not documented a self-sustaining breeding population of mountain lions in Iowa at this time. THE IOWA DNR HAS NOT 'STOCKED' OR INTRODUCED MOUNTAIN LIONS INTO THE STATE NOR IS THERE ANY CONSIDERATION OF DOING SO.

With the methods of deer hunting that take place in Iowa, one would expect to get more reports of mountain
lions during that time. Overall however, the $150,000+$ deer hunters seldom report a sighting of a mountain lion during their hunting activities. We actually receive more reports of mountain lion sightings during the summer when wildlife cover is at its maximum than we do in the winter when it is at its minimum. It is an interesting trend and not exactly sure why.

DNA testing is used to determine the origin of mountain lions that are killed in Iowa whenever possible. The origin of the 4 dead mountain lions have been completed and results indicate that they are of North American origin. Results from that testing have shown strong indications that it matched DNA common to cats from the Black Hills region of South Dakota and parts of Nebraska. There are some indications the only legal source of captive mountain lions/cougars should be of South American origin, although more study is necessary before that theory can be substantiated or discounted.

## Currently the mountain lion

 has no legal status in the Iowa Code, thus they are not given any sort of protection by Iowa Law.Although the DNR does not advocate the indiscriminate killing of mountain lions, the few mountain lions that do wander into Iowa are often shot. The DNR requested that the 2002 legislative session consider legislation to designate the mountain lion and the black bear as furbearers, thus allowing the DNR to properly manage these species, should their numbers increase. The DNR also requested that indiscriminate killing of these animals not be allowed unless they are about to cause damage or injury to property or persons. The legislation did not pass. Afterward, the Governor's office asked the DNR to not pursue mountain
lion/cougar and black bear furbearer status in the Iowa Code in 2006, 2007, and 2008.

## Depredation:

This past year, we had some cases of livestock damage/depredation but none were positively confirmed as mountain lion. In almost all cases, it was from dogs or self-inflicted injuries on fences or gates around the stock pens or pastures. These reports came from the following counties: Humboldt, Clay, Palo Alto, Kossuth, Emmet, and Bremer. Another report came from Cerro Gordo County of a horse being killed, but a direct report didn't come in time to examine the site or the animal, so that case is unknown for sure what caused it. Whenever possible, DNR staff made an effort to examine the evidence left at the scene before trying to say for sure what the predator might have been. Most depredation cases in Iowa are from canines (dogs or coyotes). It is possible for a mountain lion to attack/ depredate livestock, however again, we did not have any cases in Iowa in 2013 where we could determine for sure whether a mountain lion caused livestock damage. However, mountain lion researchers believe that white-tailed deer and other wild animals, especially mammals, are the preferred prey.

Even so, predators are generally opportunists and if hungry they will take what is readily available. We have had at least 3 reports ( 1 in Jasper, 1 in Allamakee, and 1 in Palo Alto County) from people who believe that they have seen mountain lion cubs. A few additional reports of mountain lion cubs have been reported this past year. At this point most DNR personnel are skeptical of those reports because of a lack of evidence when the area was investigated. All mountain lions that have been killed in Iowa in recent years
have all been reproductively immature 1 to 2 year old males. To date, we do not have a documented breeding population of mountain lions in Iowa. Credible mountain lion sightings and tracks are important to the Iowa DNR. Two excellent websites to help with mountain track identification are http://www.bearracker.com/cougar.html and http://www.geocities.com/Yosemite/915 2/cougar.html. It is important to remember that all cat tracks are round in shape; with 4 toes and a heel pad that has 3 posterior lobes and a less than prominent M shape on the forepart of the heel pad (Figure 2). Adult mountain lion/cougar tracks are 4 inches or larger in diameter, whereas bobcat tracks are nearer to the $21 / 2$ to 3 inch range in diameter. All cats have retractable claws, thus the tracks they leave show no claw marks except in unusual circumstances. When possible, good plaster casts of suspected tracks will aid greatly in their identification. We will continue to monitor and map reliable sightings, but because there are still many mountain lion/cougar sightings that are reported with poor quality photos or video and so few tracks found, they are difficult to substantiate.

## SAFETY ISSUES:

The good news is that lions generally avoid humans. People are more apt to be killed by a dog or struck by lightning than attacked by a mountain lion/cougar.

Some safety do's and don'ts can be found at the Mountain Lion Foundation website, www.mountainlion.org.

Also the Eastern Cougar Network is a source of Mountain lion/cougar information. Their website is mdowling@courgarnet.org.

Here are some suggestions on what to do in the remote chance you have a mountain lion/cougar encounter:
(1) Spread your jacket, coat or shirt above you head attempt to look larger.
(2) Hold your ground, wave, shout and don't run, as running stimulates the predator reflex (just like dogs) to pursue anything that runs away.
(3) Maintain eye contact if you sight a lion. Lions prefer to attack from ambush and count on the element of surprise
(4) If small children are present, or if there are several people in your group, gather everyone very close together. Mountain lions are not predators of large groups.

In the past 110 years 66 people have been attacked by mountain lions/cougars, resulting in 61 injuries, 19 of which were fatal, and none occurred in Iowa. In 2010, the DNR published a 4 fold brochure on the Status of Mountain Lions/Cougars in Iowa for the State Fair. The brochure is available on the Iowa DNR website and we send it out whenever needed to interested individuals or the media. This brochure is updated annually.

Since the first modern reports of mountain lion/cougars sightings began to increase significantly in 2001, Ron Andrews (previous Iowa DNR Furbearer Biologist, now retired 2011) gave well over 250 public informational meetings statewide regarding the status of mountain lions/cougars in Iowa and the Midwest. This was done to educate the public about Mountain Lions and help with their concerns. More mountain lion information is being put on the dnr's website and outreach efforts continue. It's important to the Iowa DNR to work with the public on this topic.

Numerous additional sighting have been reported, but are not mapped because of less than credible information. 8-21-14

## BLACK BEAR STATUS IN IOWA 2001 to Present

Black bears were one of the most recognizable and noticeable mammals encountered by Europeans as they settled North America. As settlers moved west, they generally killed any bears they encountered. Thus, black bear numbers declined rapidly in many areas and disappeared from much of their former range. Most present-day Iowans probably associate black bears with some of our large national parks and do not realize they once occurred in Iowa. When the settlers reached Iowa, they found them widespread throughout the state but higher numbers occurred where there were more woodlands. Bears were killed because they would damage crops, harass and kill livestock, and because they were valuable both as food and for their hides. Several black bear stories of the exploits of early-day "Davy Crocketts" in Iowa have been recorded in journals and diaries.

There are pre-1900 records of black bears from 48 Iowa counties, twothirds of them from counties in the eastern half of Iowa. The last recorded historical bear sighting in the 1800s was one killed near Spirit Lake in 1876. Although a Fish Commission had been established in 1873 nothing really happened in terms of Game/Wildlife legislation until after the last black bear had disappeared. Thus they are not recognized as a designated wildlife species in the Iowa Code. In the 1960s, black bear reports began to occur in the state. Several of these reports were from captive bears that were either turned loose or were escapees. In the 1990s through the present, we began to field more reports of what appeared to be wild free ranging black bears in the state.

Currently, the nearest established wild populations of black bears are in Wisconsin, Minnesota, and southern Missouri. These populations are expanding their range towards Iowa from both the north and south. Figure 1 shows the most recent sightings of bears in Iowa. Many of those confirmed reports are occurring in northeast/eastern Iowa. During 2002 alone, there were at least 5 different fairly reliable black bear sightings. In 2003 and 2004, no reliable sightings were reported. However during the spring and summer of 2005, the Iowa DNR received its first modern day black bear depredation complaint. In Allamakee County, a black bear reportedly was marauding several beehives in a few scattered locations foraging on both the bees and the honey. In 2008, a surge of 5 black bear sightings occurred, 1 in each of the following counties: Davis, Johnson, Winneshiek, as well as one shot in both Franklin and Fremont counties a week apart. Although not validated, the circumstantial evidence seems to indicate the one shot in Franklin County may have been and escaped or released bear while the one in Fremont County appears to be wild as it had been seen in Missouri, just days before it was killed just across the border from where it was last seen in Missouri.

In July (2009), a male black bear entered the northeast part of the state and paralled the eastern Iowa border south before crossing the Mississippi returning to Wisconsin. This bear crossed the Mississippi River near Harpers Ferry in Allamakee County moved westward then south and basically paralleled the river southward to near Clinton. Then it
crossed the Mississippi River near Green Island, Iowa back into Wisconsin then northward to Baraboo, Wisconsin where it became impossible to keep track of it because it had no specific markings.

During May of 2010, there was a reliable report of an adult black bear and a yearling spotted just west of Marquette, IA (Clayton County) feeding at bird feeders. In late May, 2010, a smaller bear, probably a yearling, was witnessed in northwest Mitchell County near Carpenter, IA. In early June, a bear was seen north of Northwood (Worth County) near the Iowa/Minnesota border. Observations of this bear have also reported in southern Minnesota. It would seem unlikely that this bear was the same one reported near Marquette as it was not reported at any point between and in Iowa that would be unusual as there is so much open territory to see the bear. All indications are that these are wild, free ranging bears, not bears released or escaped from captivity.

In October 2010 a black bear was sighted in and around the Yellow River Forest in Allamakee County. This prompted the Iowa Department of Natural Resources to issue a warning for people to avoid the animal at that time. This bear is likely a young male that moved into Iowa from southern Wisconsin where there is a healthy wild bear population.

In September 2011, a black bear was sighted in Winneshiek County. Again, this is likely to be a wandering bear from southeast Minnesota or southwest Wisconsin. A few unconfirmed reports came from Mitchell County along the upper Cedar River as well.

In May through June 2012, a black bear was sighted multiple times in northeast Iowa. From field reports, it
seemed to make a loop through the following counties: Winneshiek, Fayette, Chickasaw, Mitchell, Howard, and back to Winneshiek where it was last seen moving in a northerly direction. No further confirmed reports came to us after that possibly indicating it moved back into southeast Minnesota. Further reports of black bear sightings occurred there through the summer 2012.

In 2013, there were no confirmed reports of black bears in Iowa.

So far in 2014, there have been at least 3 separate reports of black bears in Iowa. One in Winneshiek/Allamakee counties, one in Fayette/Clayton counties, and one in Ringgold county. The bear seen in the Fayette/Clayton county area was reported to have two cubs with it, but the DNR hasn't been able to confirm this yet. This bear(s) is has also raided beehives causing extensive damage to the bee owner's hives.

Black bear sightings are usually more reliable than mountain lion/cougar sightings because they do not necessarily flee when sighted, also bear tracks are very distinct, and they are not readily mistaken for other animals. Black bears, like mountain lions/cougars, have no legal status in Iowa. That means they aren't protected. The DNR continues to consider legislation to give both species legal furbearer status in the Iowa Code. The Governor's office has discouraged the DNR from pursuing legal status of the black bear and mountain lion/cougar because of bio-political conflicts between agriculture and these 2 wildlife species.

Proposed legislation was introduced for designation status for the black bear, but it did not get debated during the 2006 and 2007 legislative sessions. However the public outcry over the 2 black bears shot in mid 2008 point
out that much of the public is in favor of some type of legal black bear status. The effort to give them furbearer status needs to be pursued in the future. This would allow appropriate wildlife management to occur which would include opportunities to handle nuisance black bear complaints.

Regardless of legislation, development of a more uniform and standard policy concerning bear sightings in Iowa may be warranted. A lot of emotion is generated when one of these bears are killed. Where possible we should discourage the indiscriminant killing of black bears unless there are concerns for human, pets, or livestock safety. Bears are omnivores, primarily vegetarians, foraging on seeds, fruits, berries and other plant material but given the hunger and need they will feed upon animals as well. Human tolerance will be the deciding factor as to whether black bears could ever re-established again in Iowa. If they do, their numbers would likely remain quite small.

Most historical information in this report is from Dr. James J. Dinsmore's book "A County So Full of Game-The Story of Wildlife in Iowa".

Figure 1. Black Bear Status In Iowa
(1876 Last Historical Sighting)
(Dickinson County)

## GRAY WOLF (TIMBER WOLF) STATUS IN IOWA 2001 to Present

Two large wolf-like mammals were frequently encountered by early settlers in Iowa. While Iowa was still part of the Louisiana Territory, in the early 1800s the very first piece of wildlife legislation was that to encourage killing wolves. Much of the legislation centered around bounties. There are no known specimens preserved in museums from the state. Historians usually did not distinguish between the gray (timber) wolf, Canis lupus and the coyote, Canis latrans often called the "prairie wolf." Both species were greatly persecuted and until very recently, only the coyote remains and thrives in the state.

Two different subspecies of gray wolf occurred in Iowa. The Great Plains wolf (a name that causes considerable confusion because the coyote which was often given a similar name, (the prairie wolf) was found over the western twothirds of the state. The Great Plains Wolf followed the bison herds, feeding on the stragglers from the herd as well as other prey (Dinsmore, 1994). The other subspecies was the gray (timber) wolf found primarily in eastern Iowa, especially in the wooded northeastern corner of the state. Gray wolves were likely extirpated by the late 1800s. Bowles (1971) regards the last valid wolf record to be from Butler County in the winter of 1884-85. A timber wolf taken in Shelby County in 1925 appeared to be wild, but it also could have escaped from captivity before being shot. Gray wolves often fed on the domestic animals that settlers brought to Iowa, and there are numerous reports of them killing chickens, pigs, calves, and sheep in Iowa. Gray wolves
were fully protected in all the 48 states in August of 1974 under the Endangered Species Act (ESA) of 1973.

## Great Lakes Population of Gray Wolves

In 1978, they were reclassified (down-listed) from endangered to threatened under the ESA in Minnesota. The US Department of Interior's Fish and Wildlife Service administers the ESA. The Fish and Wildlife Service is working to allow more state rights’ management of gray wolves and other resident species. Taking the gray wolf off the endangered/threatened list has continued to generate considerable controversy between wildlife professionals and animal rights' activists. Public review and input of this effort continues.

Both Minnesota and Wisconsin were allowed to move forward with their first modern day wolf harvest season that first took place in the Fall/Winter 2012.

## Rocky Mountain Population of Gray Wolves

The Rocky Mountain wolf population was delisted from threatened on July 18, 2008 which allowed them to be legally harvested with approved state management plans, however an injunction by animal rights activists placed them back on the Threatened List which in essence gave them protection again. Court disputes between activist groups, ranchers, and government agencies continued for the next few years.

The gray (Timber) wolf was officially delisted from the Endangered and Threatened on March 6, 2009. The
back and forth between federal protection or delisting has continued since. However, many western states now allow wolves to be readily killed if there is concern for the welfare of livestock. Numerous animals have, in fact, been taken since this occurred.

## Gray Wolf Status in Iowa

Unlike the moutain lion and the black bear, the gray (timber) wolf is designated as a furbearer with state protected status under the Iowa Code. Gray wolves likely have protection status because they were not clearly separated from the coyote in early bounty legislation, while Moutain Lions and Black Bear had basically been extirpated before any wildlife legislation occurred. Thus wolves are listed as a furbearer under Iowa code and are protected by state law. We currently have a closed season but a gray wolf could be killed if it was causing livestock damage. When the Great Lakes population of gray wolves were listed as threatened and endangered by the US Fish and Wildlife Service they also had federal status in Iowa. Now that the northern great lakes population has recovered and been delisted there is no federal oversight or penalty.

Beginning in the mid-1990s, a few wolves were appearing in westcentral Wisconsin and southeast Minnesota which is approximately 75 miles from the Iowa border (Figure 2). It's very likely major river corridors, especially the Mississippi River, in this tri-state region (MN, WI, IA) serve as travel corridors for wolves. Because this Driftless region is relatively rugged there is some habitat available that is conducive to wolves. It's not likely that wolves will visit Iowa often, nor in high numbers, however it is entirely likely
for the occasional wolf to come down into Iowa from Minnesota or Wisconsin (Figure 1).

In October of 2000, a radio collared wolf from Michigan was shot and killed near Kirksville, Missouri. This animal traveled over 600 miles (Straight line from where it was radio collared to where it was killed) and could have actually moved through a portion of Iowa before being killed in Missouri. Kirksville is located about 50 miles south of Bloomfield, IA.

On November 15, 2002, a wolf was shot in Houston County, Minnesota which is adjacent to Allamakee County, Iowa; the northeastern most county of Iowa. Rodney Rovang, manager of the Effigy Mounds National Monument near Marquette, Iowa, indicates that he has observed occasional wolf tracks in and near Allamakee County over the past decade.

Two known wolf-like animals were taken in 2010 in Sioux and Guthrie County.

Wolves are very mobile animals and as they extend their range southward more will likely frequent Iowa.

Plans are underway to revise Iowa's Gray Wolf Management Plan as required under the removal of the gray wolf from the Threatened list. Now that the gray wolf has been removed from the Threatened list in Minnesota, we are planning to revise the plan to accommodate the newly designated status of the gray wolf in the Midwest. The revised version will serve as a guide as to how the DNR should respond to wolf concerns as wolf numbers increase and human and wolf encounters occur.

During 2009 through 2012, a few reports have come from people seeing what they believed were gray wolves in

Iowa on a more frequent basis but we have not been able to validate their presence with any sort of solid evidence. For example, one (unconfirmed) report was in Jefferson County in July 2012.

## 2013

There were no confirmed reports of wolves in Iowa for 2013. However, there were some additional reports to the Iowa DNR that weren't able to be confirmed. Missouri and Illinois both reported $2-4$ documented wolves in their states in 2013.

## 2014

So far in 2014, the Iowa DNR was able to confirm that two female wolves were shot and killed. One was shot in February in Buchanan County, the second was shot in Jones County. Both weighed close to 70 pounds and neither showed indications that they had welped. It is likely they were both 2 year olds based on tooth wear, body size, and other features. DNA evidence on one wolf indicated it matched somewhat with the Great Lakes population of wolves. It is likely both of these wolves
travelled on their own into Iowa from MN, WI, or MI. Missouri also reported a female gray wolf was shot in the south eastern part of the state in January 2014.

It is possible that we may continue to have a roving wolf move into or through our state on rare occasion, but it's important to understand that we don't have a breeding population at this time. Time will tell whether or not a breeding population of gray wolves will become established in Iowa. Because gray wolves, at a distance can be readily mistaken for coyotes or in some cases dogs, many reports will likely be cases of mistaken identity. Modern day coyote hunters should take extra care to identify their target before shooting because it's now possible (although the chances are small), that it could be a gray wolf.

Table 1. Public reports of wolf sightings in Iowa by year (2012-2014).

| Year | Confirmed Wolf Sightings | Unconfirmed Wolf Sightings |
| :---: | :---: | :---: |

# 2013 Bowhunter Observation Survey Iowa Department of Natural Resources 

Chris S. Jennelle, Ph.D., Biometrician, lowa DNR<br>William R. Clark, Ph.D., Professor, Iowa State University

The lowa Department of Natural Resources (DNR) solicited responses from bow hunters for the annual Bowhunter Observation Survey from October 1 to December 6, 2013. This was the tenth year of the survey, which was designed jointly with William R. Clark, Professor at lowa State University. The two primary objectives for this survey are to: 1) provide an independent supplement to other deer data collected by the DNR; and 2) develop a long-term database of selected furbearer data for monitoring and evaluating an index of species activity (rate of species observation). Bowhunters are a logical choice for observational-type surveys because the methods used while bowhunting deer are also ideal for viewing most wildlife species in their natural environment. In addition, bowhunters typically spend a large amount of time in bow stands: more than 40 hours/season is not uncommon. We believe avid bowhunters (defined as those purchasing a license three years in a row prior to the survey year) are the best hunters to select for participation in this survey because they not only hunt often, but they also have the most experience in selecting good stand locations, controlling or masking human scent, using camouflage, identifying animals correctly, and returning surveys.

Participants for the 2013 survey were selected either from a core list of avid bowhunters that indicated interest in the survey from 2010, or from a list of avid bowhunters who had purchased a license for each of the 3 years prior to 2013. Our goal was to select approximately 999 bowhunters in each of lowa's 9 climate regions. Each climate region contains approximately 11 counties, and approximately 91 bowhunters were selected per county in an effort to evenly distribute observations in each region. Selection of participants consisted of a 3 -step process. In each county, participants were first randomly selected from a core group of avid bowhunters who had previously indicated an interest in participating in this survey. If fewer than 91 core group participants existed in a county, additional participants were randomly selected from a separate list of avid bowhunters who were not in the core group. Finally, if the number of "core group" and "randomly selected" participants in a county was less than 91, additional avid hunters were selected from other counties in the region to reach the regional goal of 999 participants. A total statewide sample of 8,991 bowhunters was selected for participation. Of surveys mailed, 145 were either returned due to USPS address issues or hunters indicated they did not hunt this year, making the final statewide sample 8846.

Responses were obtained from 1,710 bowhunters who recorded their observations during 24,482 hunting trips, yielding 83,411 hours of total observation time ( $3.41 \pm 0.058$ hours/trip; mean $\pm 95 \% \mathrm{CL}$ ). Bowhunters reported a median of 14 trips during the 67 -day season. Regionally, the number of bow hunting trips (and hours hunted) ranged from 1,664 ( 5,089 hours) in northwest lowa (Region 1) to 4,023 ( 13,679 hours) in east central lowa (Region 6). The raw survey response rate was 19\%.

Observations were standardized for each of the 12 species to reflect the number of observations per 1,000 hours hunted in each of the 9 regions. In addition, $95 \%$ confidence limits were calculated for each estimate. Precision among estimates for common species, such as deer, wild turkeys, and raccoons, was high: confidence limits were generally within $\pm 15 \%$ of the mean estimate. However, for less common species, such as badgers, bobcats, gray fox, and otters, precision was very low and there was considerable uncertainty in the mean estimate.

A comparison of results from 2012 and 2013 suggests that the number of total deer observed/1,000 hours decreased across all nine regions of lowa. Turkey observations decreased significantly in regions 2 and 3 (and possibly in 6,7 , and 9 ), while remaining consistent in the rest of lowa. Bobcat observations $/ 1,000$ hours remain low, but stationary across each region of the state.

We at the DNR thank all hunters who participated in the 2013 Bowhunter Observation Survey. The volume of information provided by bowhunters could never be duplicated by the staff of biologists, technicians, and conservation officers in the lowa DNR. Iowa's bowhunters are the best group of hunters to provide this observational information, and their participation in this survey plays a critical role in the conservation of these and other wildlife species for the future.

## RUFFED GROUSE

## HISTORICAL PERSPECTIVE

History: Ruffed grouse (Bonasa umbellus) were found nearly statewide in lowa during the mid-19th century but deforestation and grazing of timber caused a dramatic decline of grouse populations (Klonglan and Hlavka 1969). Ruffed grouse had disappeared from southwest lowa by 1900 and further population declines occurred in the south and east-central portions prior to the 1920's.

Grouse were restricted to their present range in the northeast 6 counties by 1930 (Fig. 2.9). Between 1930 and the early 1960's there was an increase in available and potential grouse habitat in southern and eastern lowa primarily from secondary succession of private forests and the acquisition and removal of state lands from grazing.

## HUNTING SEASONS

Although limited in distribution the existing populations in northeast lowa have persisted and provided limited hunting opportunity. The first modernday hunting season was in 1968, after a 44-year continuously closed season. Current hunting season format was established in 1981 and has varied only to assure the season opens on a Saturday.

## FALL RUFFED GROUSE SURVEY

Estimates of ruffed grouse harvest and hunter effort were historically obtained from the annual Small Game Hunter Survey. The sampling strategy
associated with this survey was primarily designed to estimate the annual harvest and hunter effort for species that have somewhat large population distributions (i.e., distributed across all or most of lowa). However, ruffed grouse have a distribution that is primarily limited to northeast lowa, and the sampling strategy was less than optimal for estimating ruffed grouse harvest and hunter effort. In addition, ruffed grouse harvest is limited to the northeast lowa grouse hunting zone while the harvest of all other small game is allowed statewide.

In 2008, ruffed grouse were removed from the small game hunter survey and the lowa Ruffed Grouse Survey was initiated. This survey has two primary goals: (1) to obtain an estimated rate that grouse are encountered by squirrel, turkey, and deer hunters, and (2) obtain an estimate of the number of grouse flushed, grouse harvested, and days hunted by ruffed grouse hunters. The sampling frame for the Iowa Ruffed Grouse Survey consists of all individuals who obtained a regular hunting license and reside in one of 14 counties that coincide with the grouse hunting zone in northeast lowa. The limited sampling frame suggests that any estimates of grouse harvest and hunter effort should be considered minimum estimates because individuals residing outside of the 14-county area may also hunt and harvest grouse in the grouse hunting zone. The sampling design for this survey uses stratified random sampling whereby individuals are selected at random from each of 14 strata (i.e., counties) to help ensure the sample is distributed across the entire
grouse hunting zone. The survey consists of two mailings: postcards are initially mailed to 3,500 individuals in mid-February and a second follow-up mailing is sent to nonrespondents in late March. Responses are returned via prepaid business reply mail to the Boone Wildlife Research Station. Postcards are electronically imaged and data are entered using OCR, ICR, and OMR technology. Data are verified by DNR personnel and validated through the use of predetermined validation rules. Further accuracy checks are performed by routines written in SAS programming language. Missing values are inputted using the Hot Deck procedure of PRECARP, and estimates are calculated using SAS PROC SURVEYMEANS and the SAS SMSUB macro.

2012-2013 Survey: Hunters surveyed in NE Iowa (Allamakee, Blackhawk, Bremer, Buchanan, Chickasaw, Clayton, Delaware, Dubuque, Fayette, Howard, Jackson, Jones, Linn, and Winneshiek) reported observing an average of 13.8 grouse per 1000 days of hunting, which was higher than the previous year of 7.0 grouse per 1000 days (Table 2.13). On average, it took hunters 72.5 days to detect a grouse, was lower than the previous year of 141.4 days. An estimated 503 ruffed grouse hunters
spent an estimated total of 2,786 days hunting for grouse in 2012-13. The previous year, 445 grouse hunters spent 6,143 total days hunting grouse. For the 2012-13 season, an estimated 373 ruffed grouse were flushed by grouse hunters, which was lower than the 523 estimated the previous year (statistically significant). For the 2012-13 season, zero ruffed grouse were reported to have been harvested, which was the same in previous year (Table 2.14). Low sample size of the grouse surveys make reliable harvest estimates difficult to determine, since very few hunters actively seek ruffed grouse as game in lowa. Previous ruffed grouse hunters and harvested grouse were estimated with the small-game survey from 1969 2010 (Table 2.15). During the last three years of the survey, estimates of harvested grouse and grouse hunters were minimal, since the small-game survey was conducted across the entire state. The new ruffed grouse surveys are focused in NE Iowa (lowa's ruffed grouse population range), thus increasing the potential to survey grouse hunters and grouse detected by general hunters.

It was decided in 2013 not to conduct the grouse survey annually. The survey will now be conducted on a 3 year rotation.
