DUBUQUE AIR QUALITY SURVEY

On 4 December 1972 the mobile air pollution control laboratory, operated by personnel of the State Hygienic Laboratory, was taken to Dubuque, Iowa for a short-term ambient air quality survey. The survey was conducted during a 12-day period from 4 December through 14 December 1972. Sites were selected to be as representative as possible of the general surrounding area and to provide maximum data on industrial emission impact to the city of Dubuque. Three sampling sites were selected for use during the survey. Mr Art Roth, City Health Administrator, cooperated with us in selecting appropriate locations and in obtaining permission for their use during the survey. Two sampling sites had been used in the previous survey conducted in November, 1971. The first collection site at 925 Kerper Boulevard is located in the industrial area very near the electrical generating plant serving the city of Dubuque. The second site at the Kirby Building is located in a commercial and industrial area in the south portion of the business district of Dubuque. A third site, residential in nature, had been selected for use but a heavy snowfall during the sampling period prevented access to that site.

Hi-volume air sampling data indicates suspended particulate levels to be in excess of the Environmental Protection Agency (EPA) 1975 standards. The geometric mean for suspended particulates during the two week survey in Dubuque was 78.7 micrograms per cubic meter which is slightly above the 75 mg/M^3 standard set by EPA. However, none of the samples exceeded the 260 mg/M^3 maximum 24-hour concentration as established by EPA standards.

Coefficient of haze data (COH) correlated reasonably well with data for suspended particulates. The geometric mean of 0.39 COH is very close to the 0.4 COH per thousand lineal feet, annual geometric mean used by the city of St Louis as a standard. We are using the St Louis standard since there are no federal or Iowa standards for coefficient of haze. COH values for Dubuque were considerably higher than those experienced in the previous survey and higher than what has been found in surveys in different parts of the year in other areas of the state.

Sulfur dioxide was detected occasionally during the survey, but values recorded were well below the primary and secondary standards for oxides of sulfur as established by EPA for 1975. It is anticipated that sulfur dioxide levels would have been considerably higher had wind direction during the time of the survey been blowing the effluent from the power plant and other industries toward the mobile laboratory. During the entire survey the ambient temperature was below 32°F so we assume that solid fossil fuel was being used by most industry in Dubuque for heating and electrical generating purposes. This solid fuel usage should have produced sulfur dioxide levels in the ambient air at higher values than were detected.

The maximum SO₂ concentration recorded was 0.044 parts per million (ppm) or approximate 1/3 of the 0.14 ppm maximum allowed in a 3-hour period by EPA standards. Wind rose data indicates that the air mass movement was away from the sampling site and directly up the river channel, making site relocation to optimize SO₂ pick up virtually impossible.

Carbon monoxide levels were higher in the commercial-industrial location at the Kirby Building than at the industrial site. This is the expected phenomena which occurs due to the heavier traffic concentration in the commercial area of any city. However, none of the carbon monoxide values approached the 1975 EPA standard. The highest 1-hour concentration for carbon monoxide was 25 ppm or about 60% of EPA 1-hour standard of 35 ppm CO. The maximum 8-hour concentration was 6.4 ppm or approximately 75% of the 9 ppm EPA standard. One reason for the low CO values obtained is that air mass movement through Dubuque was fairly constant and of sufficient velocity to cause dispersion and diffusion so that major concentrations could not accumulate.

Ozone levels showed the usual cyclical fluctuation from a minimum of 1 part per billion (ppb) to a maximum of 28 ppb, expressed as 1-hour averages during the day. The 1-hour average of 28 ppb is approximately 35% of the EPA 1975 standard of 80 ppb for photochemical oxidants.

In conclusion, this survey showed that air quality in Dubuque meets the EPA 1975 primary standards except for suspended particulate materials with respect to the parameters measured during this observation segment.

Surveys at other times of the year and under different meteorological conditions would undoubtedly produce slightly different results, with sulfur dioxide and ozone probably being higher than those demonstrated in this survey.

Because of the short-term nature of this study, data should not be considered as a comprehensive treatment of overall air quality in Dubuque, but rather as an evaluation of those specific parameters under conditions existing during the survey.

NATIONAL PRIMARY AND SECONDARY
AMBIENT AIR QUALITY STANDARDS

Primary Standard - level of air quality necessary, with an adequate margin of safety, to protect the public health.

Secondary Standard - levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

Particulate Matter (primary)

a. $75 \mu\text{g}/\text{m}^3$ - annual geometric mean

b. $260 \mu\text{g}/\text{m}^3$ - maximum 24-hour concentration not to be exceeded more than once per year.

Particulate Matter (secondary)

a. $60 \mu\text{g}/\text{m}^3$ - annual geometric mean

b. $150 \mu\text{g}/\text{m}^3$ - maximum 24-hour concentration not to be exceeded more than once per year.

Sulfur Oxides (primary)

a. $80 \mu\text{g}/\text{m}^3$ (0.03 ppm) - annual arithmetic mean

b. $365 \mu\text{g}/\text{m}^3$ (0.14 ppm) - maximum 24-hour concentration not to be exceeded more than once per year.

Sulfur Oxides (secondary)

a. $60 \mu\text{g}/\text{m}^3$ (0.02 ppm) - annual arithmetic mean

b. $260 \mu\text{g}/\text{m}^3$ (0.1 ppm) - maximum 24-hour concentration not to be exceeded more than once per year.

c. $1,300 \mu\text{g}/\text{m}^3$ (0.5 ppm) - maximum 3-hour concentration not to be exceeded more than once per year.

Carbon Monoxide (primary and secondary)

a. $10 \text{ mg}/\text{m}^3$ (9 ppm) - maximum 8-hour concentration not to be exceeded more than once per year.

b. $40 \text{ mg}/\text{m}^3$ (35 ppm) - maximum 1-hour concentration not to be exceeded more than once per year.

Ozone Standard (primary and secondary)

160 ug/m³ (0.080 ppm or 80 ppb) - maximum 1-hour concentration not to be exceeded more than once per year.

Non-methane Hydrocarbons (primary and secondary)

0.24 ppm - maximum 3-hour concentration (6 am to 9 am) not to be exceeded more than once per year.

Oxides of Nitrogen (primary and secondary)

0.05 ppm annual arithmetic mean

Coefficient of Haze

St Louis Soiling Index - 0.4 COH/1000 lineal feet, annual geometric mean.
