## 1982 PAVEMENT SMOOTHNESS MEASUREMENTS

### INTRODUCTION

The Special Investigations Section of the Office of Materials tested approximately nine hundred and five (905) miles of new paving and resurfacing for smoothness in 1982 on two hundred and thirty-four (234) individual projects. The Bureau of Public Roads (BPR) Roughometer, Iowa-Johannsen-Kirk (IJK) Roadmeter and 25-Foot Profilograph were used for 1982 smoothness testing, and test results are tabulated and summarized in this report.

PAVEMENT SMOOTHNESS MEASURING  
EQUIPMENT

Bureau of Public Roads (BPR) Roughometer:

The Roughometer was developed by the Bureau of Public Roads in 1941, and the Iowa State Highway Commission built its first Roughometer according to Bureau of Public Roads plans in 1953. The BPR Roughometer consists of a single-wheeled trailer towed behind a test van at 20 m.p.h. An integrator accumulates vertical movement in one direction only of the test wheel axle relative to the BPR trailer frame. When one inch of movement is accumulated, the integrator sends an electrical impulse to counters in the test van. The resulting Road Roughness Index (R.R.I.) is reported in Inches/Mile; lower BPR Roughometer numbers indicate smoother paving or resurfacing.

Figure 1  
BPR Roughometer  
Test Van

The integrator on the BPR Roughometer detects and accumulates short wavelength bumps up to 14 feet and minor surface deviations such as marks caused by screed settlement, straightedges, mops, vibratory rollers, stop-go movement of astro-turf drags, etc. The effect of longer wavelength bumps from 14 feet to 18 feet may be exaggerated, and long wavelength bumps over 22 feet are relatively ignored by the BPR Roughometer at 20 m.p.h. The BPR Roughometer is repeatable, rugged and reliable, but does not detect long wavelength bumps and can be affected by excessively deep or coarse transverse grooving on p.c.c. paving and sprinkle treatment on a.c. resurfacing.

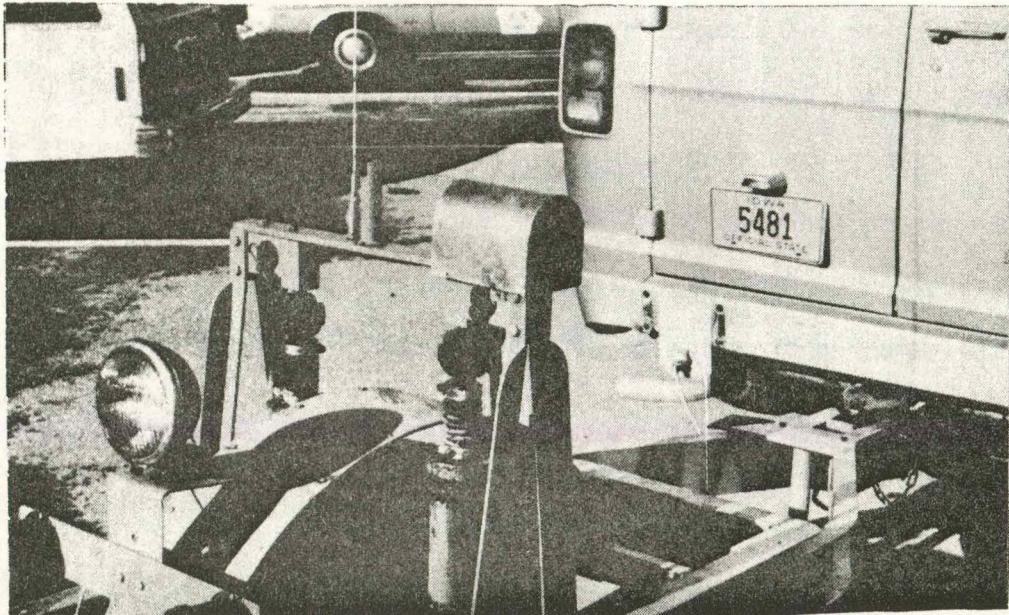

Figure 2

Closeup of BPR Roughometer

The Materials Department of the Iowa State Highway Commission began pavement smoothness testing with the BPR Roughometer in 1955 and performed this inventory of new construction yearly until 1972 when it was discontinued. Pavement smoothness testing of new construction with the BPR Roughometer resumed in 1978 and has been conducted yearly to date.

Iowa-Johannsen-Kirk (IJK) Roadmeter:

The IJK Roadmeter was developed in the Iowa State Highway Commission Materials Laboratory in 1971. It operates at 50 m.p.h. and replaces the old PCA type roadmeter which was sensitive to wind. The IJK Roadmeter consists of an electro-mechanical sensing device bolted directly to the differential housing of an ordinary passenger car. A cantilevered sprung mass moves along a contact board as bumps are encountered and sends electrical impulses to counter banks in the passenger compartment. Counters are numbered from one to ten and record the frequency and magnitude of bumps. The resulting sum/length value is converted to a Present Serviceability Index (PSI) for reporting purposes. Higher PSI's indicate smoother paving.

Figure 3  
IJK Roadmeter Vehicle

The IJK Roadmeter is more sensitive to long wavelength bumps than to short wavelength bumps and minor surface deviations. IJK Roadmeter data is fast and economical to obtain and simulates what the traveling public feels at 50 m.p.h. The problem with roadmeters has historically been poor repeatability. Trunk access to check the oil level in the IJK Roadmeter dampening mechanism several times daily has improved repeatability since 1979 to about  $\pm$  2% ( $\pm$  0.08 PSI) throughout the entire testing season.

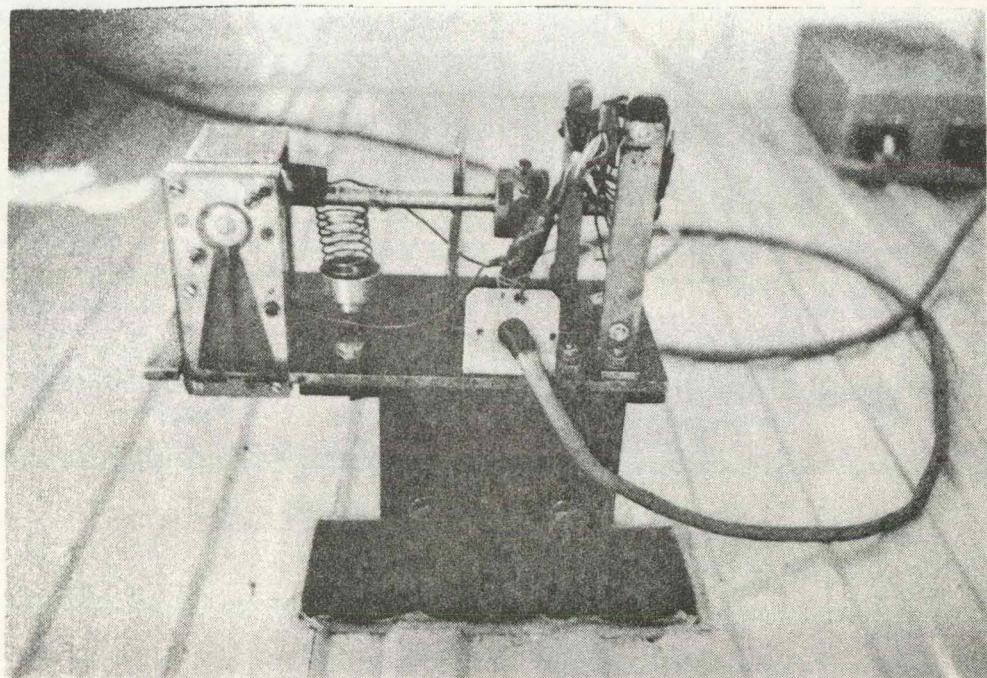

Figure 4

IJK Roadmeter Sensing Device

The IJK Roadmeter will read about 0.45 PSI lower on a.c. paving and resurfacing than on p.c.c. paving of comparable smoothness due to equations developed during the AASHO Road Test in the late 1950's.

The IJK Roadmeter is presently used to determine the Present Serviceability Index (PSI) of the Primary and Interstate road systems on a three-year cycle and to test all new construction yearly, which has been conducted since 1980.

California 25 Foot Profilograph (Profilometer):

The 25-Foot Profilograph consists of a lightweight aluminum truss supported at the end points by six (6) averaging wheels and pushed at walking speed. A bicycle wheel measures deviations from a 25 foot reference plane and is connected to a graphical recording box. The resulting 25-Foot Profilograph trace has a scale of 1 inch = 25 feet horizontally, and 1 inch = 1 inch or full scale vertically.

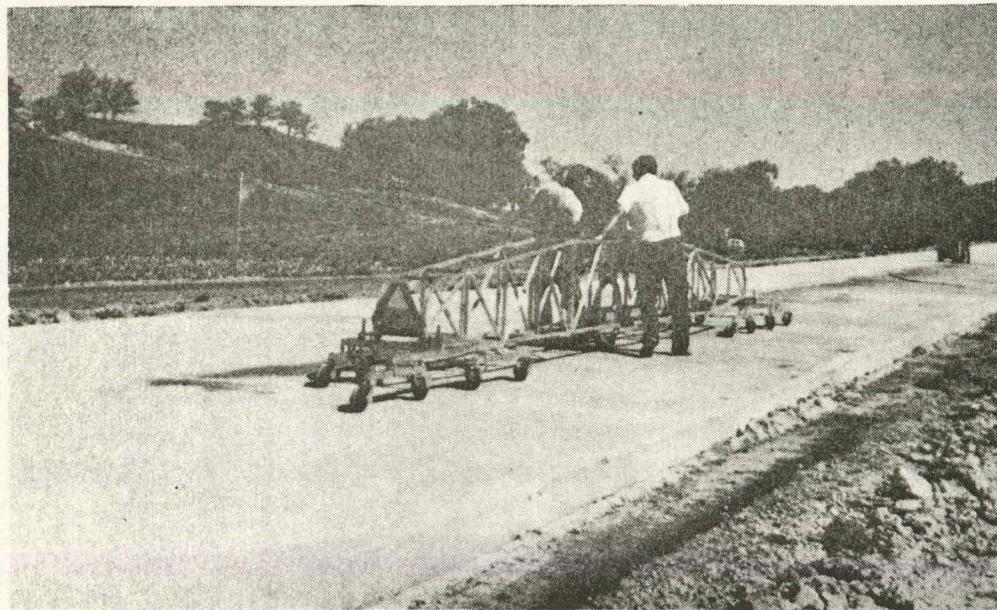

Figure 5

25-Foot Profilograph

Minor deviations less than 0.20" are "blanked out" on the 25-Foot Profilograph trace and discounted. 25-Foot Profilograph results are reported in Inches/Mile; lower 25-Foot Profilograph readings indicate smoother paving.

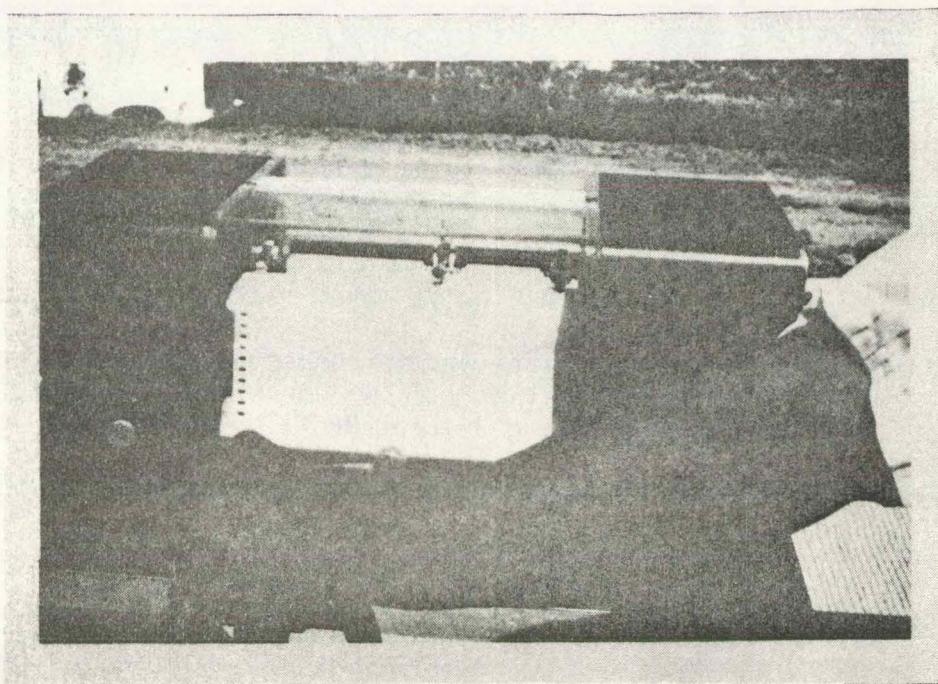

Figure 6

25-Foot Profilograph Recording Box

The 25-Foot Profilograph was used in 1982 to test all Primary and Interstate mainline pavement for compliance with Iowa DOT Specification #895 entitled "Supplemental Specification for Pavement Smoothness, December 5, 1981."

The Iowa DOT has six (6) 25-Foot Profilographs, one in each District, which were operated by District Materials' personnel during the 1982 construction season. Most 25-Foot Profilograph readings in this report represent the entire project length, although a few secondary projects were tested for information only and represent part of the project length.

1982 PAVEMENT SMOOTHNESS  
COMPARED TO PAST YEARS

Figure #7 illustrates pavement smoothness trends from 1955 thru 1982 as measured by the BPR Roughometer for new portland cement concrete slipform paving, asphaltic concrete paving, and asphaltic concrete resurfacing. Portland cement concrete slipform paving has increased 29 inches/mile, asphaltic concrete paving has increased 20 inches/mile, and asphaltic concrete resurfacing has increased 19 inches/mile, respectively, since 1972.

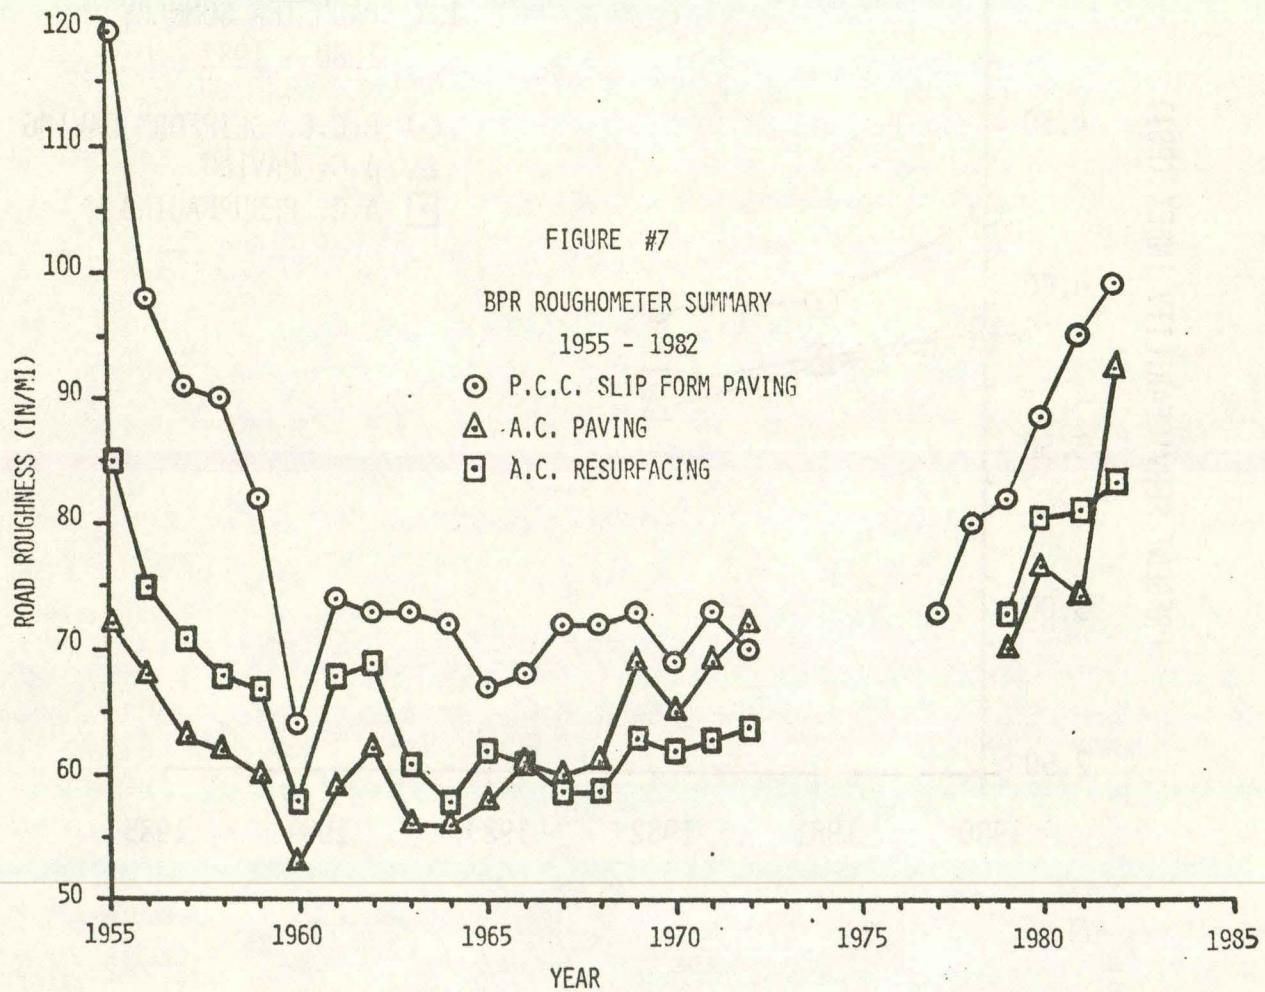

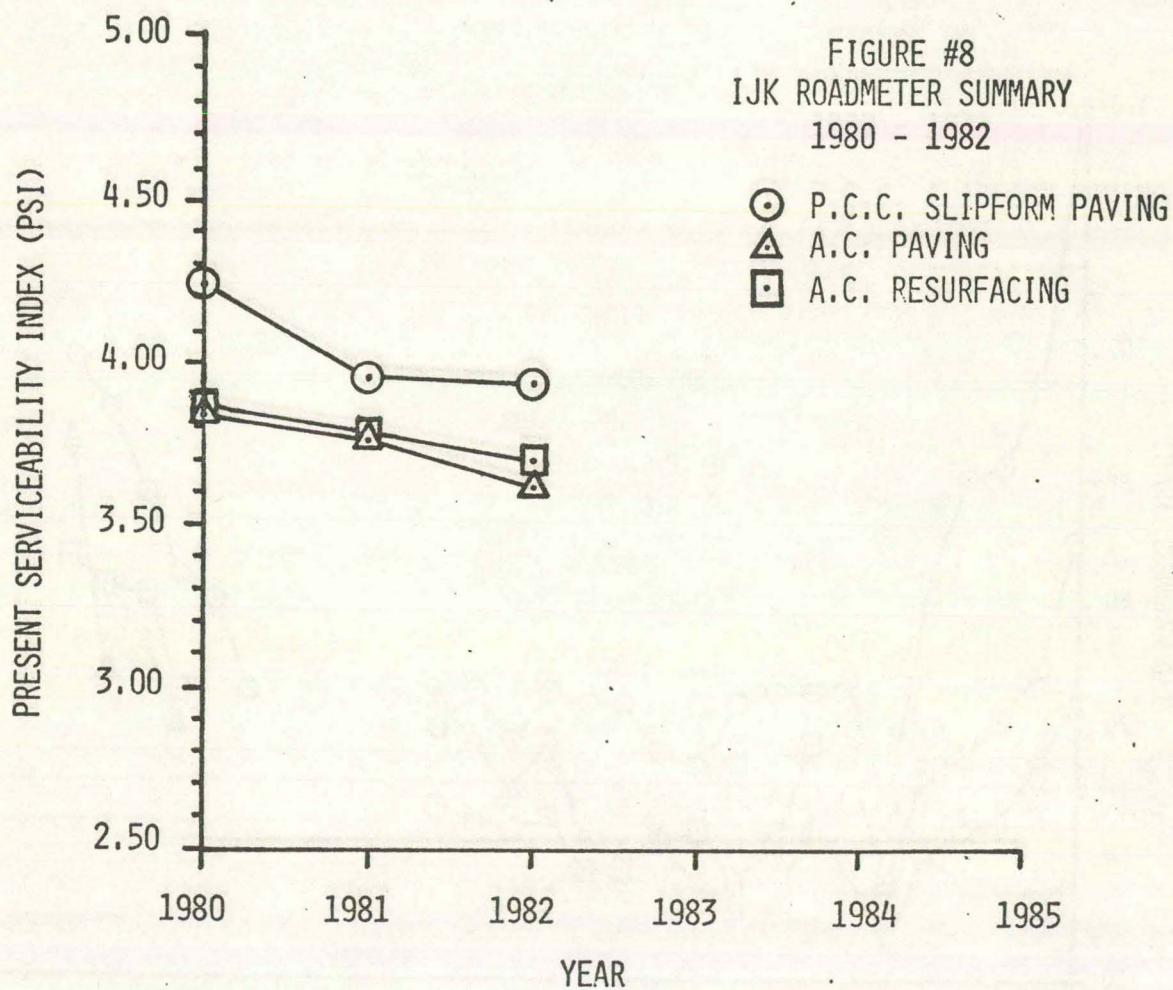

Figure #8 illustrates pavement smoothness trends between 1980 and 1982 as measured by the IJK Roadmeter for new portland cement concrete slipform paving, asphaltic concrete paving, and asphaltic concrete resurfacing. Portland cement concrete slipform paving decreased 0.04 PSI in smoothness between 1981 and 1982, while asphaltic concrete paving decreased 0.15 PSI and asphaltic concrete resurfacing decreased 0.07 PSI during the same period.

Increased roughness on new portland cement concrete slipform paving and primary asphaltic concrete resurfacing may be due in part to transverse grooving and sprinkle treatment, respectively. These texturing methods are specified for improved wet weather pavement frictional qualities. Although a study of 1977 and 1978 p.c.c. paving projects with and without transverse grooving indicated that transverse grooving has no apparent effect on pavement smoothness, increased roughness on new p.c.c. slipform paving in recent years has corresponded chronologically with the introduction of transverse grooving. One 1977 transversely grooved paving project tested as low as 46 inches/mile, and while the uniform texture of transverse grooving need not cause a problem, it can affect pavement smoothness when it is excessively coarse. Other factors affecting p.c.c. slip-form paving smoothness in recent years may include:

1. Poor subgrade conditions.
2. Insufficient stringline tension.
3. Stop-go paving machine operation resulting in screed settlement and stop-go movement of astroturf drags.
4. New paving machines, such as the Rex Town and Country and slipform Pave-Saver Citipave, having not worked as well from a pavement smoothness standpoint as the old Rex STR-type paver. This is probably due to the lighter weight and shorter track length of new paving machines.
5. Placing new p.c.c. paving over old a.c. pavement or over old broken concrete without using a track line cut by CMI fine-grading machine.

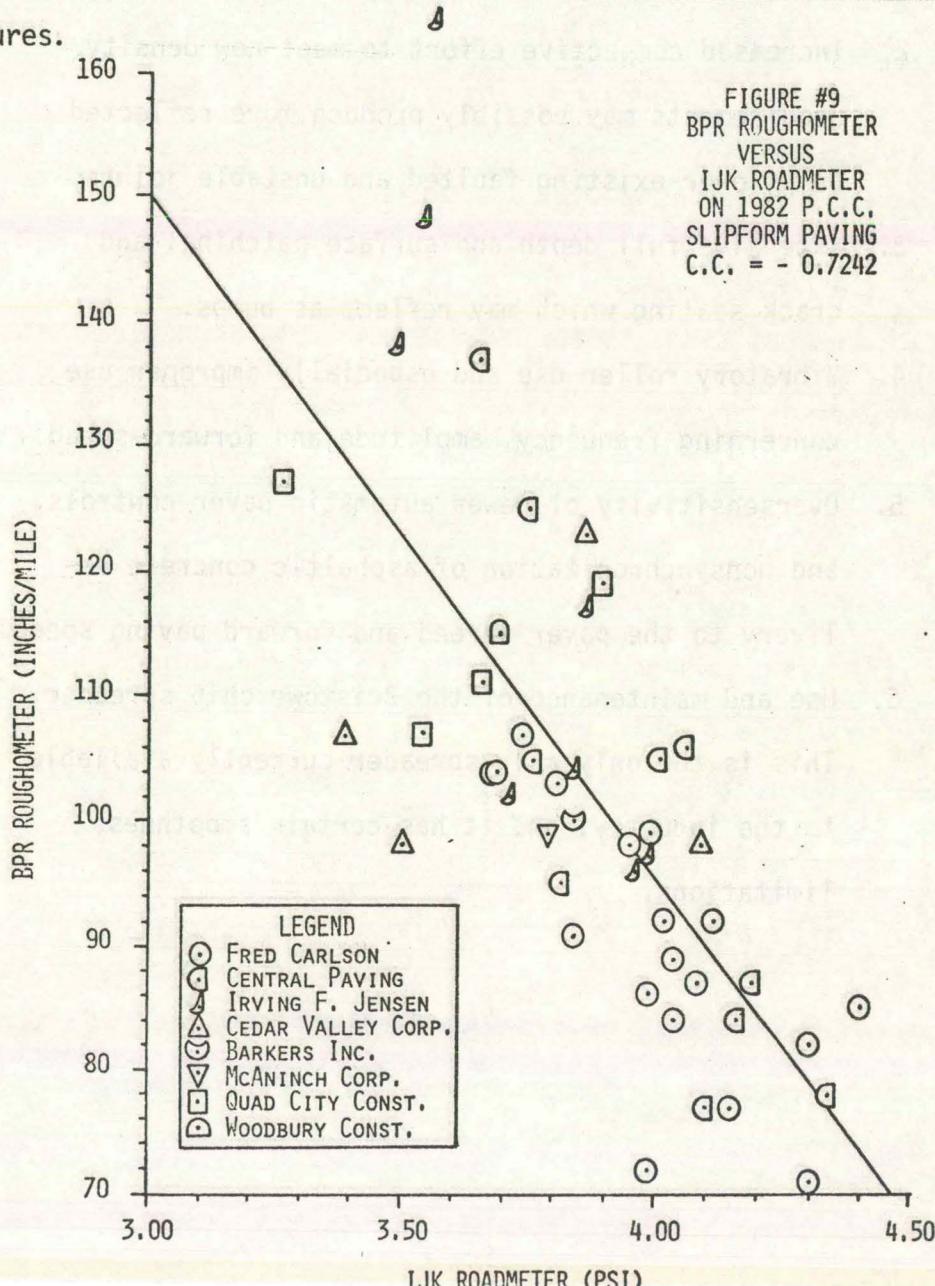

6. Non-uniform placement of concrete in front of paving machines. Piles of concrete tend to lift the new lighter paving machines.
7. Malfunctioning of paving machine sensors.

Sprinkle-treated primary rural asphaltic concrete resurfacing projects have averaged approximately 15 inches/mile rougher than nonsprinkle-treated projects in recent years. This is due to the random chip placement which is detected and integrated by the BPR Roughometer. Other factors affecting a.c. paving and resurfacing smoothness in recent years may include:

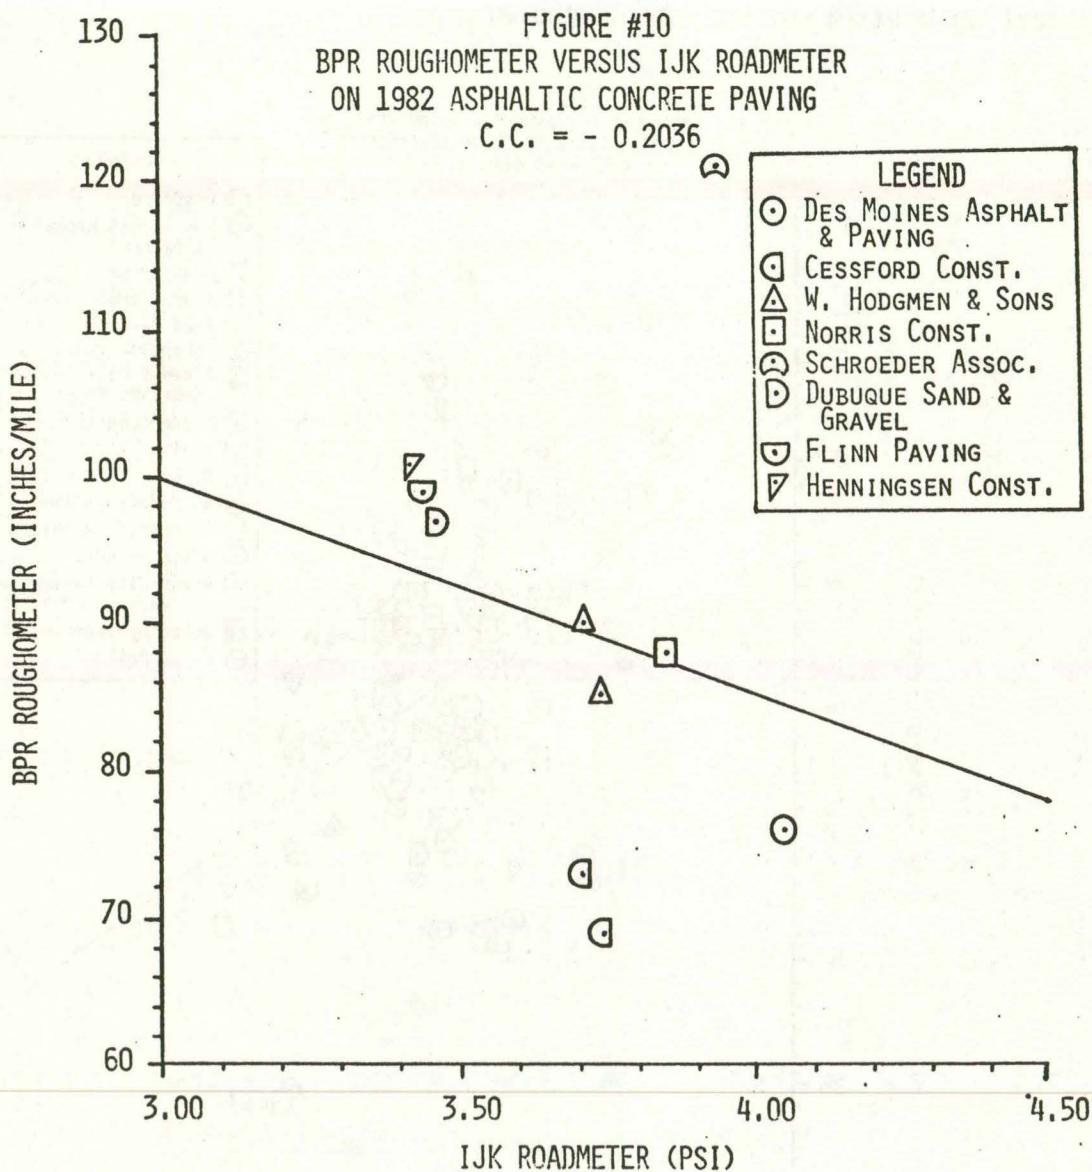

1. More single lift and thin lift a.c. overlays to stretch roadway funding as compared to multiple lift a.c. overlays or reconstruction in past years.
2. Increased compactive effort to meet new density requirements may possibly produce more reflected bumps over existing faulted and unstable joints.
3. Extensive full depth and surface patching, and crack sealing which may reflect as bumps.
4. Vibratory roller use and especially improper use concerning frequency, amplitude and forward speed.
5. Oversensitivity of newer automatic paver controls, and nonsynchronization of asphaltic concrete delivery to the paver screed and forward paving speed.
6. Use and maintenance of the Bristow chip spreader. This is the only chip spreader currently available to the industry, and it has certain smoothness limitations.

IOWA-JOHANNSEN-KIRK (IJK) ROADMETER  
COMPARED TO BUREAU OF PUBLIC  
ROADS (BPR) ROUGHOMETER ON  
1982 PAVING AND RESURFACING

The relationship between the IJK Roadmeter and BPR Roughometer on 1982 p.c.c. slipform paving, 1982 a.c. paving, and 1982 a.c. resurfacing is illustrated in Figure Number 9, Figure Number 10, and Figure Number 11, respectively. The correlation coefficients were generally poor since these machines work on different operating principles, test at different operating speeds, and are sensitive to different types of roughness. Projects with the best pavement rideability are located at the lower right-hand corner of these figures.

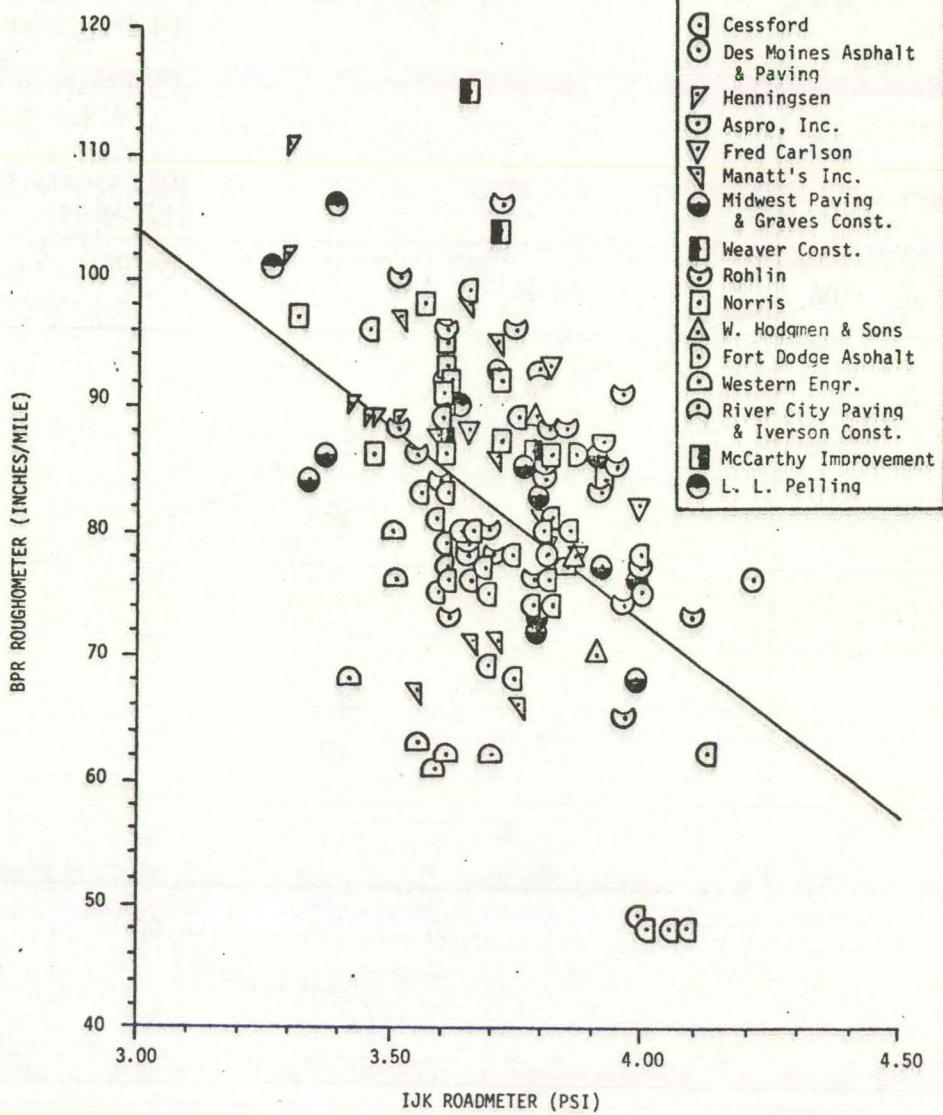

Since the IJK Roadmeter works on an inertia principle, operates at 50 m.p.h. and is sensitive to long wavelength bumps such as "dips" and "swells," it provides a better smoothness indication as felt by the travelling public than the BPR Roughometer, which operates at 20 m.p.h. and is sensitive to short wavelength bumps or "chatter."

IJK Roadmeter testing costs about \$10 per two-lane mile, requires two people and utilizes an ordinary passenger car. BPR Roughometer testing costs about \$45 per two-lane mile, requires three people and utilizes a test van and one safety vehicle.

It is desirable to use both the IJK Roadmeter and BPR Roughometer to test new construction for pavement smoothness since these machines test for different types of roughness. If only one machine must be selected, however, the best choice would be the IJK Roadmeter since it provides an initial PSI for pavement management purposes and also has lower testing costs than the BPR Roughometer.

FIGURE #12  
BPR ROUGHOMETER VERSUS IJK ROADMETER  
ON 1982 ASPHALTIC CONCRETE RESURFACING  
C.C. = -0.4727

Projects and contractors are listed in descending order in the following tabulations as ranked by the IJK Roadmeter. When projects or contractors have identical smoothness as measured by the IJK Roadmeter, they are ranked by the BPR Roughometer. All projects could not be tested with the IJK Roadmeter due to speed zones or their extremely short lengths. These projects were inserted in tabulations by inspection based on BPR Roughometer readings.
